ABSTRACT

A dispenser having an interior portion that is dimensioned for receiving a wheeled cart that is configured for storing items to be dispensed from the dispenser. The cart may, for example, be supported by at least two non-swiveled wheels disposed adjacent a first end of the cart and at least one swiveled wheel disposed adjacent a second end of the cart. In particular embodiments, the dispenser includes a pivotable wheel support that is adapted for: (A) supporting the cart's non-swiveled wheels; and (B) while supporting these non-swiveled wheels in respective, substantially fixed positions relative to the pivotable wheel support, pivoting from: (1) a first position in which the cart is positioned outside the dispenser; to (2) a second position in which the cart is positioned within the dispenser's interior. This may assist in loading the cart into the dispenser.

APPARATUS FOR INSERTING A CART, SUCH AS A CART WITH ONE OR MORE FIXED WHEELS, INTO AN ENCLOSURE

CROSS REFERENCE TO RELATED APPLICATIONS

This application is a continuation-in-part of U.S. patent application Ser. No. 11/778,422, filed Jul. 16, 2007, entitled "Guides and Other Apparatus for Inserting a Cart, Such as a Cart With One or More Fixed Wheels, Into an Enclosure", which is a continuation-in-part of U.S. patent application Ser. No. 11/744,387, filed May 4, 2007, entitled "Methods and Apparatus for Inserting a Cart, Such as a Cart With One or More Fixed Wheels, Into an Enclosure". The contents of both of these applications are hereby incorporated herein by reference in their entirety.

BACKGROUND OF THE INVENTION

Automated dispensers are currently used to dispense soft drinks, food items, toiletries, and other items to users. In hospitals, such automated dispensers may be used to distribute linens, surgical scrubs, and other items to members of the hospital's staff.

In many situations, it is desirable to load items to be dispensed from a dispenser into a cartridge at a central location and then later insert the loaded cartridge into the dispenser so that items from the cartridge may be dispensed from the dispenser. In some cases, the dispenser may use an automated door to selectively control access to the contents of the cartridge.

In various dispensers, it is desirable to load the dispenser through the front of the dispenser, so that the front portion of the cartridge aligns with a front opening of the dispenser. This is fairly easy to accomplish with cartridges that include only swiveled wheels. However, cartridges with only swiveled wheels are often difficult and unsafe to transport in populated areas such as hospitals due to their lack of stability.

There is currently a need for dispensers that would facilitate the loading, into a dispenser's housing, of cartridges having one or more non-swiveled (e.g., fixed) wheels. More particularly, there is a need for dispensers that would facilitate the lateral loading of cartridges having stable, non-swiveled wheels into the dispenser (e.g., through a front opening in the dispenser).

SUMMARY OF THE INVENTION

Dispensers according to various embodiments of the invention have an interior portion that is dimensioned for receiving a wheeled cart that is configured for storing items to be dispensed from the dispenser. The cart may, for example, be supported by at least two non-swiveled (e.g., fixed) wheels disposed adjacent a first end of the cart and at least one swiveled wheel disposed adjacent a second end of the cart. In particular embodiments, the dispenser includes a pivotable wheel support that is adapted for: (A) supporting the cart's non-swiveled wheels; and (B) while supporting these non-swiveled wheels (e.g., in respective, substantially fixed positions relative to the pivotable wheel support) pivoting from: (1) a first position in which the cart's non-swiveled wheels are positioned outside the dispenser; to (2) a second position in which the cart's non-swiveled wheels are positioned within the dispenser's interior. During this process, the cart is preferably moved so that the cart is disposed entirely within the dispenser when the wheel support is in the second position. In

various embodiments, the cart's swiveled wheels may be used to facilitate the movement of the second end of the cart into the dispenser.

A method, according to various embodiments of the invention, of loading a cart into a dispenser comprises the steps of: (1) providing a cart having a first end and a second end, the cart comprising at least one swiveled wheel adjacent the cart's first end, and at least two non-swiveled wheels adjacent the cart's second end, the swiveled and non-swiveled wheels being adapted to facilitate the rolling movement of the cart over a surface; (2) positioning the at least two non-swiveled wheels on a pivotable wheel support so that the non-swiveled wheels are supported by the pivotable wheel support; and (3) while the non-swiveled wheels are supported by the pivotable wheel support in respective, substantially fixed positions relative to the pivotable wheel support, moving the cart so that the pivotable wheel support pivots between: (A) a first position in which at least a particular one of the cart's non-swiveled wheels is disposed outside the interior portion of the dispenser; and (B) a second position in which the particular non-swiveled wheel of the cart is disposed within the interior portion of the dispenser. In particular embodiments, the step of moving the cart comprises moving the cart from: (A) a first cart position in which at least a portion of the cart is disposed outside of the interior portion of the dispenser; and (B) a second cart position in which the cart is disposed substantially entirely within the interior portion of the dispenser.

BRIEF DESCRIPTION OF THE DRAWINGS

Having described the invention in general terms, reference will now be made to the accompanying drawings, which are not necessarily drawn to scale, and wherein:

FIG. 1A is a perspective front view of a dispenser according to one embodiment of the invention. In this figure, the dispenser's flexible door is shown in an open position.

FIG. 1B is a perspective front view of the dispenser of FIG. 1A. In this figure, the dispenser's flexible door is shown in a closed position.

FIG. 2 is a top perspective view of a wheel support mechanism according to a particular embodiment of the invention.

FIG. 3 is a cross-sectional side view of the wheel support mechanism of FIG. 2, taken through Section A-A of FIG. 2, in which a storage cartridge is shown rolling onto the wheel support mechanism.

FIG. 4 is a cross-sectional side view of the wheel support mechanism of FIG. 2, taken through Section A-A of FIG. 2, in which a storage cartridge is shown after it has rolled onto the wheel support mechanism.

FIGS. 5 and 6 are perspective front views of a dispenser according to a particular embodiment of the invention that includes a wheel support mechanism, such as the wheel support mechanism of FIG. 2.

FIGS. 7A and 7B show side cross-sectional views of a wheel support mechanism according to a particular embodiment of the invention similar to the embodiment shown in FIG. 2, and taken through a section that corresponds generally to Section A-A of FIG. 2. These figures show the motion of a storage cartridge wheel 221 (e.g., a fixed cartridge wheel 221) as the wheel moves onto the wheel support mechanism. The body of the storage cartridge has been omitted from these figures for purposes of clarity.

FIG. 8A is a top view of a wheel support mechanism according to a particular embodiment of the invention.

FIGS. 8B and 8C are side cross-sectional views of the wheel support mechanism of FIG. 8A taken through Section A-A of FIG. 8A.

3

FIG. 9A is a top view of a wheel support mechanism according to a further embodiment of the invention.

FIGS. 9B and 9C are side cross-sectional views of the wheel support mechanism of FIG. 9A taken through Section A-A of FIG. 9A.

FIG. 10 is a side cross-sectional view of a wheel support mechanism that is similar to the wheel support mechanism of FIGS. 2-3 but that includes a first alternative ramp structure. This cross-sectional view is taken through a section that corresponds to Section A-A of FIG. 2.

FIG. 11 is a side cross-sectional view of a wheel support mechanism that is similar to the wheel support mechanism of FIGS. 2-3, but that includes a second alternative ramp structure. This cross-sectional view is taken through a section that corresponds to Section A-A of FIG. 2.

FIG. 12 is a perspective view of a wheel support mechanism that is structurally integrated with a scale.

FIG. 13 is a perspective view of the wheel support mechanism of FIG. 12, in which a storage cartridge is shown in engagement with the wheel support mechanism, and in an "off-scale" position.

FIG. 14 is a close-up view of the lower right-hand portion of FIG. 13.

FIG. 15 is a perspective view of the wheel support mechanism and storage cartridge of FIG. 13 in which the storage cartridge is shown in an "on-scale" position.

FIG. 16 is a close-up view of the lower right-hand portion of FIG. 15.

FIG. 17 is a perspective view of a dispenser in which a wheel support mechanism is structurally integrated with the dispenser, and in which the storage cartridge is in an "off scale position".

FIG. 18 is a perspective view of the dispenser of FIG. 17 in which the wheel support mechanism is in an "on scale position".

FIG. 19 is a perspective view of an alternative embodiment of a wheel support mechanism and scale combination.

FIG. 20 is a perspective view of the wheel support mechanism and scale combination of FIG. 19 in which a storage cartridge is shown in engagement with the wheel support mechanism and in an "off-scale" position.

FIG. 21 is a perspective view of the wheel support mechanism and scale combination of FIG. 19 in which a storage cartridge is shown in engagement with the wheel support mechanism and in an "on-scale" position.

FIG. 22 is a front perspective view of a dispenser having an angled ramp that is adapted for facilitating the movement of a storage cartridge onto a scale within the interior of the dispenser.

FIG. 23A is a front perspective view of the dispenser of FIG. 22 in which the storage cartridge is shown being wheeled onto the dispenser's scale.

FIG. 23B is a front perspective view of the dispenser of FIG. 22 in which the storage cartridge is shown in an "on-scale" position.

FIG. 24 is a top schematic view showing the orientation of the wheels of the storage cartridge of FIGS. 22 and 23 as the storage cartridge is in an intermediate loading position, partially within the dispenser.

FIG. 25 is a top schematic view showing the orientation of the wheels of the storage cartridge of FIGS. 22 and 23 when as the storage cartridge is in a final loaded position within the dispenser.

FIG. 26 is a front perspective view of a wheeled storage cartridge jack according to a particular embodiment of the invention.

4

FIG. 27 is a front perspective view of the wheeled storage cartridge jack of FIG. 26 in which the wheeled storage cartridge jack is being used to support the weight of a storage cartridge and to wheel the storage cartridge into the interior of a dispenser.

FIG. 28 is a front perspective view of the wheeled storage cartridge jack of FIG. 26 in which the wheeled storage cartridge jack is in a retracted position adjacent a storage cartridge. In this figure, the wheeled storage cartridge jack has been positioned on a dispenser's scale by the storage cartridge jack.

FIG. 29 is a perspective view of an alternative embodiment of a wheeled storage cartridge jack according to various embodiments of the invention.

FIG. 30 is a perspective view of the wheeled storage cartridge jack of FIG. 29 in which the cartridge jack is shown maintaining a storage cartridge in an elevated position and the storage cartridge is positioned outside of the dispenser's housing.

FIG. 31 is a perspective view of the wheeled storage cartridge jack of FIG. 29 in which the cartridge jack is shown maintaining a storage cartridge in an elevated position and the storage cartridge is positioned within the dispenser's housing.

FIG. 32 is a perspective view of a wheel guide apparatus according to a particular embodiment of the invention.

FIG. 33 is a perspective view of the wheel guide apparatus of FIG. 32 in which the wheel guide apparatus further includes various wheel guides and ramps, and a foot-pedal controlled mechanism for releasing the wheel guide apparatus' wheel lock.

FIG. 34 is a perspective view of the first wheel enclosure of the wheel guide apparatus of FIG. 33.

FIG. 35 is a perspective view of the wheel guide apparatus of FIG. 33 and a cart that is being positioned adjacent the wheel guide apparatus.

FIG. 36 is a perspective view of the front portion of the rear wheel enclosure of the wheel guide apparatus of FIG. 33.

FIG. 37 is a perspective view of the wheel lock of the wheel guide apparatus of FIG. 33.

FIG. 38 is a perspective view of a rear wheel enclosure of a wheel guide apparatus according to a particular embodiment of the invention.

FIGS. 39-43 are top views of the wheel guide apparatus of FIG. 33. These figures show the process of using the wheel guide apparatus to position a cart onto a scale. For purposes of clarity, the cart's body is represented as a transparent dashed rectangle.

FIGS. 44-46 are perspective views of a cart guide according to particular embodiments of the invention.

FIGS. 47-49 are top views of the cart guide of FIGS. 44-46. These figures show the process of using the cart guide to position a cart onto a scale. For purposes of clarity, the cart's body is represented as a transparent dashed rectangle.

DETAILED DESCRIPTION OF VARIOUS EMBODIMENTS OF THE INVENTION

The present invention will now be described more fully hereinafter with reference to the accompanying drawings, in which various embodiments of the invention are shown. This invention may, however, be embodied in many different forms and should not be construed as limited to the embodiments set forth herein. Rather, these embodiments are provided so that this disclosure will be thorough and complete,

5

and will fully convey the scope of the invention to those skilled in the art. Like numbers refer to like elements throughout.

Overview of Various Embodiments of the Invention

Various embodiments of the invention are directed to methods and apparatuses for facilitating the movement of a wheeled cart into an enclosure, such as the housing of an automated dispenser. Certain embodiments of the invention are particularly useful in facilitating the movement of a hospital cart (such as a hospital cart having a pair of substantially fixed-orientation wheels mounted adjacent a first end of the cart and a pair of swivel wheels mounted adjacent a second end of the cart). Particular embodiments of the invention are useful in allowing a user to insert the cart laterally into a dispenser (or other enclosure) and onto a scale within the dispenser while one or more of the cart's wheels is in a substantially fixed orientation. This may be useful, for example, when using standard hospital carts within the context of inventory management systems such as those described in Applicant's U.S. patent application Ser. No. 11/236,214, which is hereby incorporated herein by reference in its entirety.

In certain embodiments of these types of systems, a hospital cart is loaded with linens at a central location and then wheeled to a dispenser that is in a convenient linen distribution location within a hospital. The hospital cart is then inserted onto a scale within the dispenser and an automated access door associated with the dispenser is closed to prohibit unauthorized access to linens stored on the cart. To later access the linens, an authorized user typically swipes an access card through a card reader on the dispenser. The dispenser then automatically opens its access door to permit the user access to the linens. After the user removes the desired linens, the access door uses a scale upon which the cart is supported to determine the weight of linens removed from the cart. This information is then associated with the user and used to determine which entity (e.g., which department) should be billed for costs associated with using the linens (e.g., the laundry fees for the linens).

As noted above, in particular applications, various embodiments of the present invention are used to facilitate inserting a standard cart with at least one fixed wheel (and in many embodiments, at least a pair of fixed wheels) into the interior of the dispenser.

Overview of the General Structure of Exemplary Dispenser Components

Dispensers according to various embodiments of the invention include one or more common dispenser components. For the purpose of brevity, examples of various suitable dispenser components are described below. It should be understood that these components are intended as representative examples, and that other suitable components may be used in their place in particular embodiments of the invention.

Storage Cartridge
An exemplary storage cartridge **200** for use in various embodiments of the invention is shown in FIG. 1A. As may be understood from this figure, this storage cartridge **200** comprises a plurality of substantially horizontal, substantially rectangular, shelves **202-204** that are spaced apart from, and substantially parallel to, each other. These shelves **202-204** may be of any appropriate shape and/or structure, and may be made of any appropriate material (e.g., metal, plastic, or wood). The storage cartridge's shelves **202-204** may be supported by any appropriate support system. For example, in the embodiment shown in FIG. 1A, the storage cartridge's

6

shelves **202-204** are supported by a plurality of vertical support columns **211-214** disposed adjacent the storage cartridge's respective corners.

In various embodiments of the invention, the storage cartridge **200** is mounted to roll on one or more rolling mechanisms (such as wheels or rollers). For example, in the embodiment of the invention shown in FIGS. 1A and 1B, the storage cartridge **200** is mounted on four wheels **221-224**, and each of these wheels **221-224** is mounted adjacent a respective bottom corner of the storage cartridge **200**. In various embodiments of the invention, the storage cartridge **200** includes two wheels **221, 222** that are mounted in a substantially fixed orientation adjacent one end of the storage cartridge **200**. These "fixed" wheels **221, 222** are preferably spaced apart from, and co-facing each other. In addition, these wheels **221, 222** are preferably oriented to travel along parallel paths that extend, respectively, adjacent opposite lateral sides of the storage cartridge **200**.

In particular embodiments of the invention, the storage cartridge **200** includes two swiveled wheels **223, 224** that are mounted to swivel relative to the cart's base platform **201**. This allows the wheels' **223, 224** orientation relative to the storage cartridge's base portion **201** to change as the storage cartridge **200** moves over a support surface.

Dispenser Housing

A dispenser housing **100** according to one embodiment of the invention is also shown in FIG. 1A. As may be understood from this figure, in this embodiment of the invention, the dispenser housing **100** comprises: (1) a dispenser body **110**; (2) a scale **400**; (3) a calibration system; (4) an access door **112**; and (5) a control system. These dispenser components are discussed in greater detail below.

1. Dispenser Body

As may be understood from FIG. 1A, in one embodiment of the invention, the dispenser body **110** defines both an interior portion **114**, and a dispenser body access opening **116** through which the dispenser's storage cartridge **200** may be wheeled into the dispenser body's interior portion **114**. In various embodiments of the invention, the dispenser body's interior portion **114** is dimensioned to receive the storage cartridge **200** substantially entirely within this interior portion **114**.

2. Scale

As may be understood from FIG. 1A, in various embodiments of the invention, the dispenser **10** comprises one or more scales **400** that are adapted for weighing items within the dispenser **10**. As shown in FIG. 1A, in various embodiments of the invention, the dispenser **10** may include a scale **400** that, for example, is positioned on and/or adjacent the dispenser's floor (e.g., adjacent the upper or lower surface of the floor), or integrated into the dispenser's floor. In various embodiments of the invention, the scale **400** is dimensioned and configured so that when the dispenser's storage cartridge **200** is operably loaded into the dispenser housing **100**, the storage cartridge **200** is in weighing engagement with the dispenser's scale **400**.

In particular embodiments of the invention, the dispenser's scale **400** includes a weighing platform **404** that is positioned so that the scale's weighing surface is disposed within, or immediately adjacent, a portion of the dispenser's housing **100** that will support the dispenser's storage cartridge **200** when the dispenser's storage cartridge **200** is operatively positioned within the dispenser's housing **100**. In particular embodiments of the invention, the scale's weighing surface is disposed immediately adjacent the dispenser's floor.

In various embodiments of the invention, such as the embodiment shown in FIG. 1A, a weighing platform **404** of

the dispenser's scale **400** is dimensioned for supporting the storage cartridge **200** by, for example, engaging the lower surface of the storage cartridge's wheels **221-224**. For example, in the embodiment shown in FIG. 1A, the scale's weighing platform **404** includes two elongated wheel supports **404, 410** that are offset from, and parallel to each other, and that are spaced apart so that when the dispenser's storage cartridge **200** is in weighing engagement with the dispenser's scale **400**: (1) a first pair of the cartridge's wheels (e.g., the storage cartridge's fixed wheels **221, 222**) is supported by a first one of the wheel supports **405**; and (2) a second pair of the storage cartridge's wheels (e.g., the storage cartridge's swiveled wheels **223, 224**) is supported by a second one of the wheel supports **410**. In various embodiments of the invention, a wheel stop is provided adjacent the interior end of each wheel support **405, 410** in order to prevent the storage cartridge **200** from striking the back interior wall of the dispenser's housing **100** when the storage cartridge **200** is loaded into the dispenser's housing **100**.

It should be understood that any of a variety of suitable weighing mechanisms may be used in conjunction with the present invention. However, in one embodiment of the invention, the dispenser's scale **400** includes one or more load cells with leveling feet that are positioned (e.g., adjacent opposite lateral sides of the scale's weighing platform **405**) to support the scale's weighing platform **404**.

3. Calibration System

In various embodiments of the invention, the dispenser **100** includes one or more calibration systems for calibrating the dispenser's scale **400**. In a particular embodiment, the dispenser **10** includes a calibration system that is configured to recalibrate a scale **400** associated with the dispenser **10** in response to the scale's weight reading being below a predetermined value (e.g., which may, for example, be about equal to, or equal to, the combined weight of the scale's weighing platform **404** and the dispenser's storage cartridge **200**). In one embodiment, when the scale's weight reading falls below about the combined weight of the scale's weighing platform **404** and the dispenser's storage cartridge **200**, the calibration system assumes that the dispenser's storage cartridge **200** has been removed and therefore that the weight measured by the scale **400** should be that of the weighing platform **404** alone, which is known. In this embodiment, the calibration system calibrates the dispenser's scale **400** based on this assumption.

4. Access Door

As may be understood from FIG. 1A, in a particular embodiment of the invention, the dispenser's access door **112** may include a flexible (e.g., fabric) barrier made, for example, of a robust, tear-resistant material, such as ballistic nylon. As shown in this figure, the access door **112** may define a plurality of ring holes **120** that are vertically spaced apart (e.g., substantially evenly spaced apart along a substantially vertical axis) along the lateral sides of the access door **112**. In particular embodiments, the access door **112** includes a plurality of door attachment members **122** that, in various embodiments, are substantially ring shaped. In one embodiment, these door attachment members **122** are adapted to slideably attach the access door **112** adjacent the dispenser body's access opening **116** so that the access door **112** extends between: (1) a first substantially vertical support rod **124** that is positioned adjacent a first lateral side of the access door **112**, and (2) a second substantially vertical support rod **126** that is positioned adjacent a second lateral side of the access door **112**. In this embodiment, the access door **112** is preferably adapted to slide between: (1) a "door open" orientation in which the access door **112** is gathered into a plurality of folds adjacent a top portion of an opening defined between

the first and second substantially vertical support rods **124, 126**; and (2) a "door closed" orientation in which the access door **112** is in a substantially outstretched, planar orientation and at least substantially prevents access to an interior portion of the dispenser **100** through the dispenser's access opening **116**.

In a particular embodiment, the access door **112** comprises a plurality of at least substantially ring shaped door attachment members **122**, each of which is adapted to extend through a particular one of the ring holes **120** adjacent a particular lateral side of the access door **112**, and around a support rod **124, 126** adjacent the particular lateral side of the access door **112**.

In alternative embodiments, the dispenser's access door **112** may be, for example, a flexible door, such as those described in U.S. patent application Ser. No. 10/414,581, entitled "Reduced Friction Flexible Door", which was filed on Apr. 15, 2003, and which is hereby incorporated by reference. In certain embodiments of the invention, the access door **112** is a flexible "roll-up" door that is adapted so that the leading portion of the access door **112** slides within the plane of the dispenser housing's access opening **116** as the access door **112** is opened and closed.

Alternatively, the dispenser's access door **112** may take any other suitable configuration. For example, the access door **112** may include one or more user doors, such as those described in U.S. Patent Publication Number 2005/0060938 (application Ser. No. 10/671,301), which is entitled "Automated Sliding User Doors and Door Mechanisms for a Dispenser", and which is hereby incorporated by reference.

As shown in FIGS. 1A and 1B, in various embodiments of the invention, the dispenser's access door **112** is mounted to selectively restrict access to the dispenser body's interior portion **114**. For example, in the embodiment shown in FIG. 1, the access door **112** is mounted adjacent the dispenser body **110** so that the access door **112** may slide between: (1) an open position in which the access door **112** does not substantially restrict access to the interior portion **114** of the dispenser body **110** (See FIG. 1A); and (2) a closed position in which the access door **112** substantially restricts (and preferably prevents) access to the dispenser body's interior portion **114** (See FIG. 1B).

5. Control System

In various embodiments of the invention, the dispenser **10** comprises a control system (which may, for example, comprise a suitable computer processor and memory) that is adapted for receiving information from one or more weighing mechanisms **400** associated with the dispenser **10** (and, in various embodiments, other portions of the dispenser **10**, such as the dispenser's access door **112**), and for transmitting this information (e.g., via a suitable network such as the Internet) to a remote server (e.g., an inventory management server associated with a laundry facility).

In various embodiments of the invention, the control system is further configured for controlling access to the dispenser's contents by selectively locking/unlocking, and/or opening/closing the dispenser's access door **112** in response to certain conditions being satisfied. For example, in various embodiments of the invention, the dispenser **100** is adapted to maintain the access door **112** in a closed, locked position (and thereby restrict access to the dispenser's contents) until a user inputs valid access information into the dispenser's control system (e.g., via a dispenser user interface, such as a keypad or card reader).

In various embodiments of the invention, the control system is configured to transmit information obtained from a user (e.g., the user's access information) to a remote server

(e.g., an inventory management server, which is part of an inventory management system that is associated with a laundry facility) along with information obtained from the dispenser's weighing mechanisms **400**. This information may include, for example, the identity of the user, an organizational entity with which the user is associated (e.g., a particular hospital department), the particular time and date that the user removed items from the dispenser **10**, and/or the weight of items removed from the dispenser **10** at that particular time on that particular date. As described in greater detail below, this information may be used, for example, to track user activity and to keep track of which department should be charged for laundering the items removed from the dispenser **10**.

In various embodiments of the invention, the dispenser's control system is adapted for conveying information to a user (e.g., via a message displayed on a display screen associated with the dispenser **10**). For example, in one embodiment in which the dispenser **10** is used for distributing linen items, the control system may display a message regarding proper linen use. One such message may be, for example, "Do not use linen for cleaning up spills. Rather, use the rags available in the broom closet."

In another embodiment, the control system may display the weight of items removed from the dispenser as part of the current transaction. For example, the control system may display a message indicating that the user removed 5 lbs of linen from the dispenser during the current transaction. The control system may obtain this information, for example, by comparing: (1) the weight measured by the dispenser's scale **400** immediately before the transaction, with (2) the weight measured by the dispenser's scale **400** immediately after the transaction (e.g., immediately after the dispenser's door closes following the transaction).

Wheel Support Mechanism

In particular embodiments of the invention, the dispenser **10** includes a wheel support mechanism for facilitating the lateral movement of a storage cartridge **200** into the interior of the dispenser **10**. One such embodiment is shown in FIGS. **1A** and **1B** in which the dispenser **10** includes a dispenser housing **100**, a storage cartridge **200**, and a wheel support mechanism **300**. In this embodiment, the dispenser housing **100** and storage cartridge **200** have a structure as described in detail above. In particular, in this embodiment, the storage cartridge **200** includes two non-swiveled (e.g., substantially fixed) wheels **221**, **222** that are mounted adjacent a first end of the storage cartridge **200** and two swiveled wheels **223**, **224** that are mounted adjacent a second end of the storage cartridge **200**.

As shown in FIGS. **1A**, **1B**, and **2**, in this embodiment, the wheel support mechanism **300** includes a substantially planar, substantially horizontal base portion **302** (see FIG. **2**) that is mounted on a plurality of wheels **340-345** to facilitate the rolling movement of the wheel support mechanism **300** adjacent a support surface. The wheel support mechanism **300** further includes a first ramp member **320** that is mounted adjacent a first end of the wheel support mechanism **300**, and a second ramp member **330** that is mounted adjacent a second end of the wheel support mechanism **300**.

In a particular embodiment of the invention, the first ramp member **320** comprises a first substantially planar ramp portion **321** and a first substantially planar ramp lifting member **323** that are attached to each other along a first pivot axis **322** to form a substantially V-shaped structure. In the embodiment shown in FIG. **2**, the first ramp member **320** is pivotably mounted adjacent the wheel support mechanism **300** so that

the first pivot axis **322** is substantially co-axial with a first side edge of the wheel support mechanism's base portion **302**.

Similarly, in particular embodiments of the invention, the second ramp member **330** comprises a second substantially planar ramp portion **331** and a second substantially planar ramp lifting member **333** that are attached to each other along a second pivot axis **332** to form a substantially V-shaped structure. In the embodiment shown in FIG. **2**, the second ramp member **330** is pivotably mounted adjacent the wheel support mechanism **300** so that the second pivot axis **332** is substantially co-axial with the first side edge of the wheel support mechanism's base portion **302**. In particular embodiments, the first and second ramp members **320**, **330** are spaced about the same distance apart as the distance between the fixed wheels of a storage cartridge **200** with which the wheel support mechanism **300** is to be used.

In a particular embodiment of the invention, the wheel support mechanism **300** includes a first ramp member lock **326** that is retractably mounted adjacent an interior end of the ramp lifting member **323** so that it is adjacent a distal end of the first ramp lifting member **323** when the first ramp lifting member **323** is in a "ramp up" orientation. In this embodiment, the first ramp member lock **326** is substantially wedge shaped with an upwardly facing angled portion, and the wheel support mechanism **300** includes a spring **327** that is: (1) disposed adjacent a rear surface of the first ramp member lock **326**; and (2) adapted for urging the first ramp member lock **326** toward the ramp lifting member **323**.

As shown in FIG. **2**, this embodiment is configured so that when the first ramp lifting member **323** rotates from an upwardly angled to a substantially horizontal position, the distal end of the first ramp lifting member **323** engages the angled portion of the first ramp member lock **326** and thereby urges the first ramp member lock **326** away from the first ramp lifting member **323** until the distal end of the first ramp lifting member **323** passes the first ramp member lock **326**. The first spring **327** then urges the first ramp member lock **326** toward and over the distal end of the first ramp lifting member **323**. In this "locked" orientation, the first ramp member lock **326** physically prevents the first ramp lifting member **323** from rotating upwardly until the first ramp member lock **326** is again retracted (e.g., manually retracted by a user) against the first spring **327** into an unlocked position.

Similarly, as shown in FIG. **2**, this embodiment is configured so that when the second ramp lifting member **333** rotates from an upwardly angled to a substantially horizontal position, the distal end of the second ramp lifting member **333** engages the angled portion of the second ramp member lock **336** and thereby urges the second ramp member lock **336** away from the second ramp lifting member **333** until the distal end of the second ramp lifting member **333** passes the second ramp member lock **336**. The second spring **337** then urges the second ramp member lock **336** toward and over the distal end of the second ramp lifting member **333**. In this "locked" orientation, the second ramp member lock **336** physically prevents the second ramp lifting member **333** from rotating upwardly until the second ramp member lock **336** is again retracted (e.g., manually retracted by a user) against the second spring **337** into an unlocked position.

In a particular embodiment of the invention, the wheel support mechanism **300** includes at least one wheel guide **310** that is adapted to guide a particular one of the storage cartridge's wheels into a desired position (and, optionally, to maintain that particular wheel in that desired position) as the particular wheel rolls over the upper surface of the first ramp member **320** and adjacent the support surface **302** of the wheel support mechanism **300**. For example, in the embodi-

11

ment shown in FIG. 2, the wheel support mechanism 300 includes a pair of offset, substantially vertical walls 311, 312 that are positioned on opposite sides of the first ramp member's first ramp lifting member 323. These substantially vertical walls 311, 312 are preferably substantially parallel to the lateral sides of the first ramp lifting member 323. In various embodiments, a similar wheel guide may be provided adjacent the second ramp lifting member 333.

Wheel Support Mechanism—Operation

FIGS. 3-6 depict the operation of the exemplary embodiment of the wheel support mechanism 300 shown in FIGS. 1 and 2. As may be understood from FIGS. 3-6, a user begins by moving the wheel support mechanism's first and second ramp members 320, 330 into a "ramp down" orientation in which: (1) the respective distal ends of their respective first and second ramp portions 321, 331 touch the support surface on which the wheel support mechanism 300 is resting; and (2) the first and second ramp lifting members 323, 333 are angled upwardly relative to the base 302 of the wheel support mechanism 300. Next, the user aligns: (1) the storage cartridge's right fixed wheel 221 with the wheel support mechanism's first ramp member 320; and (2) the storage cartridge's left fixed wheel 222 with the wheel support mechanism's second ramp member 330.

FIGS. 3 and 4 show the movement of the storage cartridge's right fixed wheel 221 onto the first ramp member 320. However, it should be understood that the general movement of the storage cartridge's left fixed wheel 222 onto the second ramp member 330 is essentially the same as that shown in FIGS. 3 and 4.

As may be understood from FIGS. 3 and 4, after the alignment step referenced above, the user pushes the storage cartridge 200 toward the wheel support mechanism 300. As a result, the storage cartridge's first and second fixed wheels 221, 222 roll, respectively, onto the first and second ramp portions 321, 331. The user then continues to push the storage cartridge 200 toward the wheel support mechanism 300 until the first and second fixed wheels 221, 222 engage, respectively, the first and second ramp lifting members 323, 333, which causes the first and second ramp members 320, 330 to rotate, respectively, about the first and second pivot axes 322, 332 until: (1) the respective distal ends of the first and second ramp portions 321, 331 are angled upwardly relative to the base 302 of the wheel support mechanism 300; and (2) the first and second ramp lifting members 323, 333 are in a substantially horizontal orientation adjacent the upper surface of the base 302 of the wheel support mechanism 300.

As noted above, during this transition, the distal end of the first ramp lifting member 323 engages the angled portion of the first ramp member lock 326 and thereby urges the first ramp member lock 326 away from the first ramp lifting member 323 until the distal end of the first ramp lifting member 323 passes the first ramp member lock 326. The first spring 327 then urges the first ramp member lock 326 toward and over the distal end of the first ramp lifting member 323. In this "locked" orientation, the first ramp member lock 326 physically prevents the first ramp lifting member 323 from rotating upwardly until the first ramp member lock 326 is again retracted (e.g., manually retracted by a user) against the first spring 327 into an unlocked position.

Similarly, as the storage cartridge 200 moves onto the wheel support mechanism 300, the distal end of the second ramp lifting member 333 engages the angled portion of the second ramp member lock 336 and thereby urges the second ramp member lock 336 away from the second ramp lifting member 333 until the distal end of the second ramp lifting member 333 passes the second ramp member lock 336. The

12

second spring 337 then urges the second ramp member lock 336 toward and over the distal end of the second ramp lifting member 333. In this "locked" orientation, the second ramp member lock 336 physically prevents the second ramp lifting member 333 from rotating upwardly until the second ramp member lock 336 is again retracted (e.g., manually retracted by a user) against the second spring 337 into an unlocked position.

As shown in FIGS. 1A and 5, once the storage cartridge's fixed wheels 221, 222 are locked in place on the wheel support mechanism 300, the user: (1) aligns the wheel support mechanism 300 with the scale's first wheel support 406; and (2) aligns the storage cartridge's swiveled wheels 223, 224 with the scale's second wheel support 410. The user then pushes the storage cartridge 200 toward the scale 400 until: (1) the wheel support mechanism 300 is disposed on the scale's first wheel support 406; and (2) the storage cartridge's swiveled wheels 223, 224 are disposed on the scale's second wheel support 410, as shown in FIG. 6. In various embodiments, when the storage cartridge 200 is in this position, the storage cartridge 200 is preferably disposed entirely within the interior portion of the dispenser's housing, and the storage cartridge 200 is supported by the scale 400. This preferably allows the dispenser's access door to close without engaging the storage cartridge 200.

Alternative Embodiments of the Wheel Support Mechanism Embodiment of FIGS. 7A and 7B

FIGS. 7A and 7B show an alternative embodiment of the wheel support mechanism. In this embodiment, the wheel support mechanism's first and second ramp members 300 are structured similarly to the first and second ramp members 320, 330 shown in FIGS. 2 and 3 except that their respective first and second ramp lifting members 363 are, respectively, substantially shorter than their respective first and second ramp portions 361. Also, in various versions of this embodiment, the wheel support mechanism does not include ramp member locks for maintaining the ramp members 360 in a "ramp up" position when the storage cartridge 200 is being supported by the wheel support mechanism 300. Rather, in particular embodiments, such as the embodiment shown in FIGS. 7A and 7B, the weight of the storage cartridge 200 serves to maintain the ramp members 360 in a "ramp up" position when the storage cartridge 200 is being supported by the wheel support mechanism 300.

Embodiment of FIGS. 8A-8C

FIGS. 8A-8C show yet another embodiment of the wheel support mechanism. In this embodiment, the wheel support mechanism's first ramp member 500 has a structure that is similar to the first and second ramp members 320, 330 shown in FIGS. 2 and 3. In particular, the ramp member's ramp portion 505 is structurally the same as the ramp portion 321, 331 of the embodiment shown in FIGS. 2 and 3. However, in the embodiment shown in FIGS. 8A-8C, the first ramp member's first ramp lifting member 510 includes a substantially rectangular frame as shown in FIG. 8A.

More particularly, in this embodiment, the first ramp lifting member 510 includes two offset, substantially parallel elongated frame members 511, 512 and a roller support 513 that extends between the distal ends of the frame members 511, 512. In a particular embodiment, the roller support 513 has a substantially circular cross section and a substantially cylindrical roller 515 is rotatably mounted on the roller support 513 so that the roller 515 may rotate about the central axis of the roller support 513. In various embodiments, the roller 515 and the roller support 513 are substantially coaxial.

In particular embodiments, the frame members 511, 512 are spaced apart by a distance that is greater than the width a

13

storage cartridge wheel that the wheel support mechanism 300 is adapted to support. In addition, in particular embodiments, the first ramp member 500 includes a pair of spaced-apart, substantially vertical guide walls 506, 508 disposed on opposite sides of the first ramp member's ramp portion 505. These vertical guide walls 506, 508 are preferably adapted for guiding the wheel of a storage cartridge as the wheel moves up the ramp 505.

To use the embodiment of the invention shown in FIGS. 8A-8C, a user first aligns a storage cartridge 200 so that its first fixed storage cartridge wheel 221 is aligned with the first ramp member's ramp portion 505, and so that its second fixed storage cartridge wheel is aligned with the second ramp member's ramp portion (not shown). The user then pushes the storage cartridge 200 toward the wheel support mechanism 300 until the storage cartridge's fixed wheels 221, 222 each roll respectively up one of the wheel support mechanism's ramp members and onto the wheel support mechanism 300.

FIGS. 8B and 8C show the movement of a storage cartridge's first fixed wheel 221 onto a wheel support mechanism 300 via a first ramp member 500. As may be understood from this figure, the first fixed wheel 221 is first urged onto the ramp portion 505 of the storage cartridge's first ramp member 500. The storage cartridge's first fixed wheel 221 is then moved toward the first ramp member's roller 515 until the storage cartridge wheel 221 engages the roller 515. Next, the storage cartridge's first fixed wheel 221 is urged further against the roller 515, which causes the first ramp member 500 to rotate about its axis of rotation 507 until: (1) the first ramp lifting member 510 is in a substantially horizontal position adjacent the surface of the base 302 of the wheel support mechanism 300; and (2) the ramp portion 505 extends upwardly from the base 302 of the wheel support mechanism 300.

In particular embodiments, the weight of the storage cartridge 200 on the first ramp lifting member 510 maintains the ramp portion 505 in a "ramp up" position, such as that shown in FIG. 8C. As may be understood from this figure, in various embodiments, when in the orientation shown in FIG. 8C, the ramp lifting member 510 and the frame of the wheel support mechanism 300 cooperate to maintain the storage cartridge wheel 221 in place on the wheel support mechanism 300 (e.g., by exerting forces on opposite sides of the wheel 221).

In various embodiments, the movement of the storage cartridge's second fixed wheel onto the wheel support mechanism 300 via a second ramp member occurs in substantially the same manner as that described above in regard to the storage cartridge's first fixed wheel 221.

Embodiment of FIGS. 9A-9C

FIGS. 9A-9C show a further embodiment of the wheel support mechanism. In this embodiment, the wheel support mechanism's first ramp member 600 includes a first ramp portion 605 that has a structure that is similar to the first and second ramp portions 321, 331 shown in FIGS. 2 and 3. However, the ramp portion 605 includes a first cable support member 634 adjacent its first lateral side and a second cable support member 636 adjacent its second lateral side. In this embodiment, the first ramp member 600 further includes a ramp lifting assembly 610 that includes a substantially planar, substantially U-shaped first ramp lifting member 611 that is positioned so that it is in a substantially horizontal plane and so that its distal ends 613, 614 are positioned adjacent a pivot axis 607 of the first ramp portion 605 when the first ramp portion 605 is in a "ramp down" orientation.

As shown in FIG. 9A, in one embodiment, a first cable 630 extends between the first distal end 613 of the first ramp lifting member 611 and the first cable support member 634.

14

Similarly, a second cable 632 extends between the second distal end 614 of the first ramp lifting member 611 and the second cable support member 636. In this configuration, when the first ramp lifting member 611 moves away from the first ramp portion 605, the first ramp lifting member's first and second distal ends 613, 614 exert upward forces on the first ramp portion 605 adjacent the first and second cable support members 634, 636. This, in turn, causes the first ramp portion 605 to rotate about the first ramp portion's axis of rotation 607 and into a "ramp up" orientation (see FIG. 9C).

In particular embodiments, the first ramp lifting member 611 is supported by a pair of supports 620, 622 as shown in FIGS. 9A-9C. In particular, in various embodiments, each respective elongated straight portion of the U-shaped ramp lifting member 611 (e.g., the portions of the ramp lifting member 611 that comprise its respective distal ends 613, 615) is mounted to slide adjacent a corresponding one of the supports 620, 622. For example, in the embodiment shown in FIG. 9A, each straight portion of the ramp lifting member 611 is mounted so that it extends through a passage defined by a corresponding support 620, 622. In this embodiment, the diameter of the passage preferably has about the same diameter (e.g., a slightly larger diameter) than the diameter of each straight portion. This allows the ramp lifting member 611 to slide laterally relative to the supports 620, 622, for example, between the "ramp down" position of FIG. 9B and the "ramp up" position of FIG. 9C. This also preferably serves to maintain the ramp lifting member 611 in a substantially horizontal orientation as the ramp lifting member 611 slides between the "ramp up" and "ramp down" positions.

In particular versions of the embodiment shown in FIGS. 9A-9C, the wheel support mechanism 300 includes a second ramp member (not shown) that has substantially the same structure as the first ramp member 600. In this embodiment, the first and second ramp members are preferably positioned in a configuration similar to the first and second ramp members 320, 330 shown in FIGS. 1A, 1B, and 2.

To use the embodiment of the invention shown in FIGS. 9A-9C, a user first aligns a storage cartridge 200 so that its first fixed storage cartridge wheel 221 is aligned with the first ramp member's ramp portion 605, and so that its second fixed storage cartridge wheel 224 is aligned with the second ramp member's ramp portion (not shown). The user then pushes the storage cartridge 200 toward the wheel support mechanism 300 until the storage cartridge's fixed wheels 221, 222 each roll respectively up one of the wheel support mechanism's ramp members and onto the wheel support mechanism 300.

FIGS. 9B and 9C show the movement of a storage cartridge's first fixed wheel 221 onto a wheel support mechanism 300 via a first ramp member 600. As may be understood from these figures, the first fixed wheel 221 is first urged onto the ramp portion 605 of the storage cartridge's first ramp member 600. The storage cartridge's first fixed wheel 221 is then moved toward the first ramp member's roller 615 until the storage cartridge wheel 221 engages the roller 615. Next, the storage cartridge's first fixed wheel 221 is urged further against the roller 515. The user then continues to urge the storage cartridge 200 against the roller 515, which causes the first ramp lifting member 611 to slide horizontally away from the first ramp portion 605. This causes the first ramp member's cables 630, 632 to rotate the first ramp member's first ramp portion 605 about its axis of rotation 607 until the first ramp portion 605 is angled upwardly and disposed adjacent the first fixed wheel 221.

The user then continues to urge the storage cartridge's first fixed wheel 221 toward the first ramp member's first locking portion 650 until the first locking portion 650 (e.g., a latch)

15

lockably engages the first ramp lifting member's latching rod 612. This causes the first fixed wheel 221 to be locked in place between: (1) the first ramp member's ramp portion 605 (which is in an upright position and engages a rear portion of the first fixed wheel 221); and (2) the ramp lifting member 611 (which preferably engages a front or other portion of the fixed wheel).

As may be understood from FIGS. 9A-9C, in various embodiments, the first ramp lifting member roller 615 may be adapted to facilitate the rolling engagement of the first fixed wheel 221 with at least a portion of the ramp lifting member 611. For example, in the embodiment shown in FIGS. 9A-9C, the roller 615 may be rotatably attached adjacent (e.g., to) the ramp lifting member's curved central portion. In various embodiments, this roller 615 is adapted to rotate in response to a wheel rotatably engaging the roller 615. In various embodiments, this may prevent the wheel from exerting a downward force on the ramp lifting member 611 as the ramp lifting member 610 moves from a "ramp down" to a "ramp up" position.

Embodiment of FIGS. 10 and 11

Other exemplary embodiments of the ramp members are shown in FIGS. 10 and 11. In each of these arrangements, the first and second ramp members are positioned and hinged in a manner that is similar to the first and second ramp members shown in FIGS. 1A, 1B, and 2. However, the structural arrangement of the first and second ramp members (e.g., the structure of their respective ramp portions and ramp lifting members) is different from that of the first and second ramp members of FIG. 2.

Turning to the embodiment shown in FIG. 10, the ramp member's ramp portion 705 is generally in the form of a downwardly facing v-shaped member that includes a first substantially planar portion 706 and a second substantially planar portion 708. In a particular embodiment of the invention, the first and second substantially planar portions 706, 708 are attached to each other in an angled relationship along a common edge as shown in FIG. 10. In this embodiment, when the ramp portion 705 is in a "ramp down" orientation: (1) the first substantially planar portion 706 is angled upwardly in relation to the support surface supporting the wheel support mechanism 300; (2) the second substantially planar portion 708 is angled to extend downwardly from the inner end of the first substantially planar portion 706 to the pivot point 707 of the ramp member 700; and (3) the ramp lifting member 710 extends upwardly from the pivot point 707 of the ramp member 700, away from the second substantially planar portion 708.

In this embodiment, the angle A formed between the first substantially planar portion 706 and the support surface is preferably between about 5 and about 30 degrees. Also, in particular embodiments of the invention, the ramp member 700 is adapted so that when a wheel 221 of a storage cartridge 200 is supported by the second substantially planar portion 708 and the ramp lifting member 710 (as shown in FIG. 10), the wheel's axis of rotation is disposed within substantially the same vertical plane as the ramp member's pivot point 707.

A method of using the ramp member 700 of FIG. 10 will now be described in regard to using the ramp member 700 to facilitate the movement of a first fixed wheel 221 of a storage cartridge onto a wheel support mechanism 300. It should be understood that this same method may be used to roll a second fixed wheel 222 of a storage cartridge (e.g., substantially simultaneously with the first fixed wheel 221) onto the wheel support mechanism 300 via a second ramp member (not shown).

16

Turning to FIG. 10, to use the ramp member 700, a user first aligns the first wheel 221 of a storage cartridge with the first ramp member 700. The user then pushes the storage cartridge up the first substantially planar portion 706 and over the peak formed by the first and second substantially planar portions 706, 708. The user then continues to push the storage cartridge toward the wheel support mechanism 300 until: (1) the first wheel 221 is supported by and between the second substantially planar portion 708 and the ramp lifting member 710; and (2) the axis of rotation of the first wheel 221 is substantially in vertical alignment with the pivot point 707 of the ramp member 700. The user then continues to push the storage cartridge toward the wheel support mechanism 300, which causes the ramp member 700 rotate about its pivot point 707 until the ramp member 700 is in a "ramp up" position.

In particular embodiments, when the ramp member 700 is in a "ramp up" position, the ramp lifting member 710 is in a substantially horizontal orientation adjacent the base 302 of the wheel support mechanism 300. In particular embodiments, the weight of the storage cartridge on the ramp lifting member 710 serves to maintain the ramp member 700 in the "ramp up" position until a user pulls the storage cartridge 300 outwardly away from the wheel support mechanism 300. In particular embodiments, when the first wheel 221 is in place on the wheel support mechanism 300 and the ramp member 700 is in a "ramp up" position, the second ramp portion 708 and a side wall portion 304 of the wheel support mechanism 700 engage opposite sides of the wheel 221 and thereby maintain the wheel 221 in a substantially fixed position relative to the base 302 of the wheel support mechanism 300.

In one embodiment, to remove the cartridge's fixed wheels 221, 222 from the wheel support mechanism, the user simply pulls the cartridge away from the wheel support mechanism 300. In response, the ramp member 700 rotates from a "ramp up" to a "ramp down" position, which allows the storage cartridge's fixed wheels 221, 222 to roll up the second substantially planar portion 708, down the first substantially planar portion 706, and off of the wheel support mechanism 300.

A further alternative embodiment of the ramp member 700 is shown in FIG. 11. In this embodiment, the ramp member 800 is structurally and functionally similar to the ramp member 700 of FIG. 10 except that the angle formed between the substantially planar portion 806 and the second substantially planar portion 808 is selected so that the second substantially planar portion 808 is disposed in a substantially horizontal position when the ramp member 800 is in the "ramp down" orientation shown in FIG. 11. In addition, in preferred embodiments of the invention, the ramp member 800 is constructed so that the angle formed between the second substantially planar portion 805 and the ramp lifting member 810 is greater than about 90 degrees.

Wheel Support Mechanism Integrated with Scale or Dispenser Housing

In some situations, it may be desirable to structurally integrate the wheel support mechanism 300 with other portions of the dispenser 10. This may be useful, for example, in maintaining the wheel support mechanism 300 in a stable position as the wheels of a storage cartridge 200 are rolled onto the wheel support mechanism 300. This may also be useful in preventing the unwanted removal (e.g., theft) of the wheel support mechanism 300.

FIGS. 12-16 show an embodiment of the invention in which the wheel support mechanism 1100 is structurally integrated with the dispenser's scale 1000. As may be understood from FIG. 12, the overall structure of the wheel support mechanism 1100 is similar to the structure of the wheel sup-

17

port mechanism 300 of FIG. 2, except that, in the embodiment shown in FIGS. 12-16, the wheel support mechanism 1100 is supported by: (1) a pair of wheels 1142, 1143 that are disposed adjacent (and preferably attached to) opposite lateral sides of the wheel support mechanism's outer end; and (2) a pair of rollers 1140, 1145 that are disposed adjacent (and preferably attached to) opposite lateral sides of the wheel support mechanism's inner end. In the embodiment shown in FIG. 12, the wheel support mechanism's first roller 1140 is adapted to roll (e.g., substantially horizontally) along a first substantially horizontal, substantially planar track 1015 that is disposed adjacent a first lateral side of the scale's first wheel support 1005. Similarly, the wheel support mechanism's second roller 1145 is adapted to roll (e.g., substantially horizontally) along a second substantially horizontal, substantially planar track 1020 that is disposed adjacent a second lateral side of the scale's first wheel support 1005.

In various embodiments, a ramp 1006 is provided adjacent the outer side of the first wheel support 1005 to facilitate the movement of the wheel support mechanism 1100 onto the first wheel support 1005. In various embodiments, this ramp 1006 is pivotably mounted adjacent the first wheel support 1005 so that the ramp 1006 may be pivoted between: (1) a "ramp down" position in which the ramp's distal end engages a support surface supporting the wheel support mechanism 1100; and (2) a "ramp up" position in which the ramp's distal end is spaced apart from and positioned above the support surface. As shown in FIG. 12, in particular embodiments, a ramp activation member 1007 extends upwardly from the ramp 1006 and is positioned in the path of a ramp actuator 1150 that is disposed adjacent a lateral side of the wheel support mechanism 1100.

In the embodiment shown in FIG. 12, the ramp activation member 1007 is adapted so that, when the ramp 1006 is in the "ramp down" position, rotating the ramp activation member 1007 toward the first wheel support 1005 causes the ramp 1006 to rotate into the "ramp up" position. Accordingly, the ramp activation member 1007 may be used to control the position of the ramp 1006.

To use the embodiment of the invention shown in FIG. 12, a user first aligns the fixed wheels of a storage cartridge 200 with the wheel support mechanism's first and second ramp members 1120, 1130 (which may be, for example, in the form of any suitable ramp member, such as those described above) and then pushes the storage cartridge 200 toward the wheel support mechanism 1100 until, as shown in FIG. 13: (1) the storage cartridge's fixed wheels (e.g., the first fixed wheel 221) are supported by the wheel support mechanism 1100; and (2) the wheel support mechanism's first and second ramp members 1120, 1130 are in a "ramp up" position. In various embodiments, when the storage cartridge 200 is in this position, the storage cartridge's swiveled wheels (e.g., swiveled wheel 223) are generally in-line with the second wheel support 1010 of the dispenser's scale.

Next, with the storage cartridge's fixed wheels locked in place on the wheel support mechanism 1100, the user pushes the storage cartridge 200 toward the dispenser's scale 1000. As may be understood from FIGS. 14 and 15, as the outer end of the storage cartridge 200 moves past the ramp 1006 and onto the scale's first wheel support 1005, the wheel support mechanism's ramp actuator 1150 engages the ramp actuation member 1007 causing the ramp actuation member 1007 to rotate toward the dispenser's scale 1000. This, in turn, causes the ramp 1006 to rotate from the "ramp down" to the "ramp up" position.

The user then continues pushing the storage cartridge 200 toward the rear portion of the scale 1000 until: (1) the wheel

18

support mechanism 1100 is disposed entirely on (e.g., is fully supported by) the scale's first wheel support 1005; and (2) the storage cartridge's swiveled wheels (e.g., swiveled wheel 223) are disposed entirely on (e.g., are fully supported by) the scale's second wheel support 1010. In this configuration, the storage cartridge 200 is preferably supported substantially entirely by the dispenser's scale 1000, which allows the scale 1000 to measure the weight of the storage cartridge 200 and any items stored on the storage cartridge's shelves. In various preferred embodiments, the dispenser 10 is dimensioned so that: (1) the storage cartridge 200 is disposed entirely within the dispenser's interior when the storage cartridge 200 is in this position; and (2) the dispenser's access door 112 can be selectively opened and closed when the storage cartridge 200 is in this position.

To remove the storage cartridge 200 from the dispenser's housing 100, the user pulls the storage cartridge 200 away from the dispenser's housing (e.g., toward the user), which causes the wheel support mechanism 1100 to exert an outward force on the inner surface of the ramp 1006 while the ramp actuator 1150 moves away from the ramp activation member 1007. This causes the ramp 1006 and the ramp activation member 1007 to rotate from the "ramp up" position to the "ramp down" position. The user then continues pulling the storage cartridge 200 away from the dispenser's housing 10 until the wheel support mechanism 1100 is fully extended. The user then pulls the storage cartridge 200 off of the wheel support mechanism 1100 as discussed above.

Embodiment of FIGS. 17-18

In alternative embodiments of the invention, an example of which is shown in FIGS. 17-18, the wheel support mechanism is integrated with the body 110 of the dispenser 10. In the embodiment shown in FIGS. 17-18, the dispenser 10 includes a substantially horizontal rod sleeve 1210 that is disposed adjacent an outer lateral side of the scale's first wheel support. A guide rod 1205 is disposed in a telescoping arrangement with the rod sleeve 1210 so that the guide rod 1205 can slide (e.g., substantially horizontally) between: (1) a first position in which a particular portion of the guide rod 1205 is within an interior portion of the rod sleeve 1210; and (2) a second position in which that particular portion of the guide rod 1205 is disposed outside of the interior portion of the rod sleeve 1210.

In this embodiment, the wheel support mechanism 1200 is similar in structure and operation to the wheel support mechanism 1100 shown in FIGS. 12-16. However, the guide rod 1205/rod sleeve 1210 arrangement described above is positioned adjacent the wheel support mechanism's outer lateral side edge so that when the guide rod 1205 and wheel support mechanism 1200 are both fully extended: (1) the guide rod 1205 is adjacent, substantially parallel to, and offset from, the wheel support mechanism's outer lateral side edge; and (2) the outer end of the guide rod 1205 is disposed adjacent the outer end of the wheel support mechanism 1200.

In particular embodiments of the invention, the distal end of the guide rod 1205 is attached to the wheel support mechanism's outer lateral side edge via a piece of lightweight flexible material 1213 (such as a lightweight string or cable). This causes the guide rod 1205 to: (1) extend in response to the wheel support mechanism 1200 being extended (e.g., out of the interior of the dispenser); and (2) retract into the rod sleeve 1210 in response to the wheel support mechanism 1200 being retracted (e.g., into the interior of the dispenser). In various embodiments of the invention, the lightweight piece of flexible material 1213 is advantageous because it adds only a negligible amount of weight to the total amount of weight

19

measured by the dispenser's scale **1000** when the storage cartridge **200** and wheel support mechanism **1200** are stored on the scale **1000**.

It should be understood that, in various embodiments of the invention, the piece of lightweight flexible material **1213** may be replaced by any other suitable mechanism for attaching the guide rod **1205** to the rod sleeve **1210**.

In particular embodiments of the invention, a roller ball (not shown) may be positioned between the guide rod **1205** and the outer portion of the wheel support mechanism **1200** that is immediately adjacent the guide rod **1205**. In various embodiments, this roller ball may be attached adjacent (e.g., to) the surface of the guide rod **1205** that co-faces the wheel support mechanism **1200**. This roller ball may serve to reduce the friction between the wheel support mechanism **1200** and the guide rod **1205**. As will be understood by one skilled in the relevant field in light of this disclosure, any other suitable friction-reducing device or material may also be used for this purpose.

In various embodiments of the invention, at least a portion of the wheel support mechanism **1200** is mounted directly to the dispenser's scale **1000**. For example, in particular embodiments, the rod sleeve **1210** is attached directly to the dispenser's scale **1000**. In such embodiments, the scale **1000** may be calibrated to take the weight associated with the wheel support mechanism **1200** into account when determining the weight of items positioned on the scale **1000**.

Slide Plate as Wheel Support Mechanism

FIGS. **19-21** show a wheel support mechanism **1301** according to yet another embodiment of the invention. As may be understood from FIG. **19**, this wheel support mechanism **1301** includes a substantially rectangular slide plate **1302** that is mounted to slideably pivot about a pivot point **1315** that is located on an outer lateral corner of the scale's first wheel support **1305**. As shown in FIG. **19**, in this embodiment, the slide plate **1302** is mounted so that the pivot point **1315** extends through a particular corner of the slide plate **1302**.

As shown in FIGS. **20** and **21**, the slide plate **1302** is configured to pivotably slide between: (1) a first position in which the slide plate **1302** extends out of the interior of a dispenser (e.g., through the dispenser's access opening **116**); and (2) a second position in which the slide plate **1302** is disposed substantially entirely within the interior portion of the dispenser's body **114**, and is supported substantially entirely by the scale's first wheel support **1305**.

In a particular embodiment, the wheel support mechanism **1301** includes an elongated ramp member **1330** that has a V-shaped cross section and that is mounted to pivot about an axis of rotation **1340** that is disposed adjacent the base of the ramp member's V-shaped cross section as shown in FIG. **19**. In particular embodiments of the invention, this axis of rotation **1340** lies substantially on and/or adjacent an outer side edge of the slide plate **1302**.

In particular embodiments of the invention, to use the embodiment of the invention shown in FIG. **19**, a user preferably positions a storage cartridge **200** so that the storage cartridge's fixed wheels **221**, **222** align with the wheel support mechanism's ramp member **1330**. The user then pushes the storage cartridge **200** toward the ramp member **1330** until the storage cartridge's fixed wheels **221**, **222** roll up the ramp portion **1335** of the ramp member **1330** and engage the ramp member's ramp lifting member **1345**. The user then urges the storage cartridge **200** against the ramp lifting member **1345**, which causes the ramp member **1330** to rotate about its axis of rotation **1340** until, as shown in FIG. **20**: (1) the ramp lifting member **1345** is in a substantially horizontal position adja-

20

cent the upper surface **1312** of the slide plate **1302**; and (2) the ramp portion **1335** extends upwardly and away from the slide plate's upper surface **1312**. The user then positions the storage cartridge **200** so that the storage cartridge's fixed wheels **221**, **222** are between the front and rear edges of the slide plate **1302**. In various embodiments, the user then positions the storage cartridge **200** so that the storage cartridge's fixed wheels **221**, **222** engage a wheel stop **1320** (see FIG. **19**) that is disposed adjacent a rear edge of the slide plate **1302**.

Next, the user pushes the end of the storage cartridge **200** adjacent which the storage cartridge's swiveled wheels **223**, **224** are attached toward the dispenser's scale **1000** until the storage cartridge's swiveled wheels **223**, **224** are positioned on the scale's second wheel support **1010** (See FIG. **21**). During this rotational movement of the storage cartridge **200**, the cart's fixed wheels **221**, **222** exert an inward force on the slide plate's wheel stop **1320**, which causes the slide plate **1302** to rotate about the slide plate's pivot point **1315** until the slide plate **1302** is supported by (and, in particular embodiments, disposed adjacent a top surface of) the scale's first wheel support **1005**. Also, in particular embodiments, the slide plate's wheel stop **1320** serves to maintain the cart's fixed wheels **221**, **222** in a substantially fixed position adjacent the slide plate **1302** as the slide plate **1302** rotates about the slide plate's pivot point **1315**.

As shown in FIG. **21**, in various embodiments, after the storage cartridge **200** is moved into this orientation: (1) the lateral sides of the slide plate **1302** are positioned substantially parallel to the rear surface of the dispenser's housing **110**; (2) the dispenser's fixed wheels **221**, **222** are positioned so that they are supported by the scale's first wheel support **1005**; and (3) the dispenser's swiveled wheels **223**, **224** are positioned so that they are supported by the scale's second wheel support **1010**. Accordingly, when the storage cartridge **200** is in this "on scale" configuration, substantially the entire weight of the storage cartridge **200** and its contents are measured by the scale **1000**.

In particular embodiments, the slide plate **1302** may be in the form of a substantially planar plate that includes a low-friction bottom surface for facilitating the sliding motion of the slide plate **1302** relative to a support surface. In various embodiments, the slide plate **1302** may be supported by wheels (or any other suitable mechanism) to facilitate the movement of the slide plate **1302** relative to the support surface.

FIGS. **22-23** show a further embodiment of a dispenser having a scale that includes two separate wheel supports **1405**, **1410** and that is adapted for weighing items that are supported by the two wheel supports **1405**, **1410**. In this embodiment, the dispenser further includes a ramp **1400** that is disposed adjacent the scale's first wheel support **1405**. In this embodiment, the ramp **1400** preferably includes a substantially planar ramp portion **1402** that is upwardly angled relative to the support surface upon which the dispenser **10** is supported. In addition, in particular embodiments, the ramp **1400**, comprises a substantially planar, substantially horizontal upper support surface **1404** at least a portion of which is disposed adjacent, and at substantially the same vertical level, as the upper surface of the scale's first wheel support **1405**. Also, in the embodiment shown in FIGS. **22**, **23A** and **23B**: (1) the scale's first wheel support **1405** defines a front edge **1409** and an interior side edge **1411**; and (2) the portion of the substantially horizontal upper support surface **1404** that is adjacent the scale's first wheel support **1405** conforms substantially to the shape of the front edge **1409** and the interior side edge **1411** of the scale's first wheel support **1405**.

21

Similarly, in other embodiments of the invention in which the ramp **1400** and the scale's first wheel support **1405** are in different structural configurations, at least a portion of the outer perimeter of the ramp **1400** may be shaped to conform substantially to the shape of the outer perimeter of the scale's first wheel support **1405**. In particular embodiments, the ramp **1400** and the scale may cooperate to form a substantially planar horizontal surface having a first substantially planar wheel support portion that is adapted for supporting the fixed wheels of a storage cartridge **200**. The scale may further include a second, substantially planar wheel support portion **1410** that is adapted for supporting the fixed wheels of a storage cartridge **200**. As noted above, the scale is preferably adapted for measuring the weight of items supported on the scale's first and second wheel supports **1405**, **1410**. The dispenser **10** shown in FIGS. **22** and **23** is a specific example of such an embodiment.

As may be understood from the embodiment of FIG. **22**, the ramp **1400** may be positioned so that the front side edge **1421** of the ramp **1400** forms an angle of between 10 and 50 degrees with: (1) the dispenser's access door **112**; (2) the dispenser's rear surface; and/or (3) the front edge of the dispenser's first wheel support portion **1405**. This may serve to facilitate the smooth positioning of the storage cartridge **200** into the dispenser's interior.

In the embodiment of the invention shown in FIGS. **23A** and **23B**, in order to insert the storage cartridge **200** into the dispenser's housing **100**, the user first aligns the storage cartridge's fixed wheels **221**, **222** so that the fixed wheels' respective paths of travel cross the ramp's ramp portion **1402**. The user then pushes the storage cartridge **200** toward the ramp **1400** until the storage cartridge's fixed wheels **221**, **222** roll up the ramp's ramp portion **1402**, onto the ramp's planar support portion **1404**, and onto the scale's first wheel support **1405**.

The user then pushes the end of the storage cartridge **200** adjacent which the swiveled wheels **223**, **224** are attached toward the scale until the storage cartridge's swiveled wheels **223**, **224** are positioned on the scale's second wheel support **1410**. As shown in FIG. **23B**, in various embodiments, after the storage cartridge **200** is moved into this orientation: (1) the dispenser's fixed wheels **221**, **222** are positioned so that they are supported by the scale's first wheel support **1405**; and (2) the dispenser's swiveled wheels **223**, **224** are positioned so that they are supported by the scale's second wheel support **1410**. Accordingly, when the storage cartridge **200** is in this "on scale" configuration, substantially the entire weight of the storage cartridge **200** and its contents are measured by the scale.

For further clarification of the storage cartridge insertion process described above, FIGS. **24** and **25** show the position and orientation of a storage cartridge **200** and its fixed wheels **221**, **222** and swiveled wheels **223**, **224**: (1) as the storage cartridge **200** is being moved into the dispenser housing **100** (see FIG. **24**); and (2) as the storage cartridge **200** is stored within the dispenser (see FIG. **25**).

Wheeled Jack Embodiment

FIGS. **26-28** show yet another embodiment of the invention that may be used to facilitate the movement of a storage cartridge **1550** (e.g., a hospital cart having both fixed and swiveled wheels) into the interior of a dispenser **10**. As may be understood from these figures, this embodiment includes a wheeled jack **1500** that is adapted to: (1) lift the storage cartridge **1550** and; (2) while supporting the storage cartridge **1550** in an elevated position, facilitate the rolling movement of the storage cartridge **1550** into the dispenser's housing **100**.

22

As may be understood from FIG. **26**, in a particular embodiment of the invention, the wheeled jack **1500** includes a base portion **1505** that is mounted on one or more rolling mechanisms (e.g., wheels **1510**, **1511**, **1512**) so that the wheeled jack **1500** may be selectively rolled adjacent a support surface (e.g., a floor supporting the wheeled jack **1500**). For example, in the embodiment of FIG. **26**, the wheeled jack **1500** comprises: (1) a substantially rectangular base portion **1505**; (2) a first pair of wheels **1510**, **1511** that are mounted adjacent a first lateral side of the rectangular base portion **1505** (e.g., adjacent the respective ends of the base portion's first lateral side); and (3) a second pair of wheels **1512** (second wheel not shown) that are mounted adjacent a second lateral side of the rectangular base portion **1505** (e.g., adjacent the respective ends of the base portion's second lateral side).

In particular embodiments, the wheeled jack **1500** further includes a support member **1520** (which may be, for example, in the form of a substantially rectangular, substantially horizontal plate) that is adapted for selectively engaging a storage cartridge **1550** and for exerting support forces on the storage cartridge **1550** that are sufficient to lift the storage cartridge **1550** off the ground and to then maintain the storage cartridge **1550** in an elevated position.

In various embodiments, the wheeled jack **1500** further includes a lifting mechanism **1525** for selectively moving the support member **1520** vertically (e.g., upwardly and/or downwardly) relative to a support surface supporting the wheeled jack **1500**. In various embodiments, this lifting mechanism may include, for example: (1) a scissors lift (as shown in FIG. **26**); (2) one or more pneumatic cylinders; (3) one or more screw mechanisms; (4) one or more hydraulic cylinders; and/or (5) any other suitable lifting mechanism.

In particular embodiments, to use the wheeled jack **1500** to insert a storage cartridge **1550** into a dispenser **10**, a user first positions the storage cartridge **200** so that the storage cartridge's rear surface is generally parallel to the front surface of the dispenser **10** and so that the storage cartridge **200** is generally laterally aligned with the dispenser's access opening (as shown in FIG. **27**). The user then positions the wheeled jack **1500** underneath the storage cartridge **1550** so that: (1) the wheeled jack **1500** is positioned laterally between the storage cartridge's fixed wheels **1553** and swiveled wheels **1551**, **1552**; (2) the wheeled jack's wheels (which may be, for example, fixed wheels) are positioned to guide the wheeled jack **1500** into the dispenser's interior (e.g., along a path that is substantially perpendicular to the dispenser's front surface); and (3) the wheeled jack's support member **1520** is spaced apart from (e.g., the bottom surface of) the storage cartridge **1550**.

Next, the user activates the wheeled jack's lifting mechanism **1525** to move in an upward direction so that the lifting mechanism **1525** moves the wheeled jack's support member **1520** substantially vertically upwardly until the support member **1520**: (1) engages the bottom surface of the storage cartridge **1550**; and (2) after engaging the bottom surface of the storage cartridge **1550**, lifts the storage cartridge **1550** off the ground and into an elevated position as shown in FIG. **27**. While the storage cartridge **1550** is in this elevated position, the user then rolls the wheeled jack **1500** toward and into the dispenser's interior until the storage cartridge's wheels are positioned on the wheel support portions **1530**, **1532** of the dispenser's scale. (For example, until: (1) the storage cartridge's fixed wheels **1553**, **1554** are positioned on the scale's first wheel support **1532**; and (2) the storage cartridge's swiveled wheels **1551**, **1552** are positioned on the scale's second wheel support **1530**.)

Finally, the user activates the wheeled jack's lifting mechanism **1525** to move in a downward direction until the storage cartridge **1550** is at least substantially supported by (e.g., entirely supported by) the dispenser's scale. In particular embodiments of the invention, in this position, which is shown in FIG. **28**: (1) the storage cartridge's fixed wheels **1553**, **1554** are positioned on and supported by the scale's first wheel support **1532**; and (2) the storage cartridge's swiveled wheels **1551**, **1552** are positioned on and supported by the scale's second wheel support **1530**. The dispenser **10** may then be used to dispense items from the storage cartridge **1550** as described above (e.g., with the dispenser's scale at least substantially continuously monitoring the storage cartridge's weight in real time). To remove the storage cartridge **1550** from the interior of the dispenser, the user may simply reverse the steps described above.

FIGS. **29-31** depict an alternative version of a "wheeled jack" embodiment of the invention. In this embodiment, a scale is integrated into the wheeled jack **1600** and used to weigh the storage cartridge **1650** when the storage cartridge **1650** is supported by the wheeled jack **1600**. For example, in the embodiment shown in FIGS. **29-31**, a scale is integrated into the wheeled jack's support member **1620**. More particularly, in this embodiment, the support member **1620** includes two substantially horizontal plates **1621**, **1622** that are spaced vertically apart from each other. These plates **1621**, **1622** are separated by one or more weight measurement devices **1661-1663** that are positioned, respectively, adjacent opposite lateral ends of the support member **1620**.

In particular embodiments, to use the wheeled jack **1600** to insert a storage cartridge **1650** into a dispenser **10**, a user first positions the storage cartridge **1650** so that its rear surface is generally parallel to the front surface of the dispenser **10** and so that the storage cartridge **1650** is generally laterally aligned with the dispenser's access opening. The user then positions the wheeled jack **1600** underneath the storage cartridge **1650** so that: (1) the wheeled jack **1600** is positioned between the storage cartridge's fixed wheels **1653** and swiveled wheels **1651**, **1652**; (2) the wheeled jack's wheels (**1610**, **1612**, **1614**) (which may be, for example, fixed wheels) are positioned to guide the wheeled jack **1600** into the dispenser's interior (e.g., along a path that is substantially perpendicular to the dispenser's front surface); and (3) the wheeled jack's support member **1620** is spaced apart from (e.g., the bottom surface of) the storage cartridge **1650**.

Next, the user activates the wheeled jack's lifting mechanism **1625** to move in an upward direction so that the lifting mechanism **1625** moves the wheeled jack's support member **1620** substantially vertically upwardly until the support member **1620**: (1) engages the bottom of the storage cartridge **1650**; and (2) after engaging the bottom surface of the storage cartridge **1650**, lifts the storage cartridge **1650** off the ground and into an elevated position as shown in FIG. **30**. While the storage cartridge **1650** is in this elevated position, the user then rolls the wheeled jack **1600** towards and into the dispenser's interior until the storage cartridge **1650** is positioned entirely within the dispenser's interior. In various embodiments, the wheeled jack **1600** maintains the storage cartridge **1650** in an elevated position (e.g., so that the wheeled jack's scales can continuously measure the weight of the storage cartridge **1650**) while the dispenser is in operation as described above.

Exemplary Operation of Dispenser's Display

In various embodiments of the invention, the dispenser **10** is adapted to display information to users, for example, via a display screen located on or adjacent the dispenser **10**. This information may be provided, for example, via a computer

that is internal or external to the dispenser **10**. In particular embodiments, the information may reflect data derived (either directly or indirectly) from information measured by the dispenser's scale.

For example, in various embodiments, the dispenser **10** may be adapted so that, in response to a user removing items (e.g., hospital linens) from the dispenser **10**, the dispenser **10** displays the weight of the items removed from the dispenser **10**. This information may be displayed, for example, immediately upon the user removing the items from the dispenser **10**, or after the dispenser's access door **112** is closed. As an example, in particular embodiments, in response to a user removing six pounds of hospital linens from a dispenser **10**, after the dispenser's access door **112** closes, the dispenser **10** will display an indication to the user (e.g., on a display screen associated with the dispenser **10**), that the user removed six pounds of hospital linens from the dispenser **10**. This information may help the user manage their overall use of linens.

As another example, the dispenser may be configured to display the average weight of particular items that other, similar users have been using under similar circumstances. For example, in the context of a particular nurse removing hospital linens from the dispenser **10**, the dispenser **10** may be configured to display (e.g., simultaneously display): (1) the weight of linen that the particular nurse has been using; and (2) the weight of linen that other nurses in the same hospital have been using under similar circumstances. This information may include, for example, the weight of linen that the nurse and other nurses have been using: (1) per hour; (2) per shift; (3) per day; (4) per patient; (5) per patient day; and/or (6) any other suitable unit of time. This may serve as an ongoing reminder to hospital staff to keep their linen usage within proper limits.

In particular embodiments of the invention, the dispenser **10** may be configured to display (e.g., simultaneously display along with one or more of the items of information referenced above), the cost associated with using the linens that the user has removed from the dispenser during the current dispenser transaction, and/or during previous dispenser transactions. In particular embodiments, this cost may include a cost that a laundry facility would charge for laundering the linens.

Exemplary Reporting Features

In particular embodiments, the dispenser and/or computer systems associated with the dispenser may be adapted to generate one or more reports that reflect data obtained from the dispenser (e.g., the dispenser's scale). In various embodiments, such reports may include: (1) one or more reports that indicate item usage (e.g., linen usage) of each user within a particular department; and/or (2) one or more reports that specifically identify users that are using excessive amounts of a particular item (e.g., hospital linens) relative to their peers. Such reports may be helpful in identifying users who are not complying with predetermined item usage guidelines.

In further embodiments, the reports may indicate the usage of items (e.g., linen) by each user within a particular department. Such reports may be used to bill each particular department for the items (e.g., linen) removed by the members of that particular department. This may, for example, serve to make a particular department manager directly responsible for the use of items (e.g., linen) within their department.

Description of Wheel Guide Apparatus

In various embodiments, a wheel guide apparatus is used to guide a cart into a desired position (e.g., a position on a scale) within a dispenser or other enclosure. A wheel guide apparatus **1700** according to a particular embodiment of the invention is shown in FIG. **32**. As may be understood from this figure, in this embodiment, the wheel guide apparatus **1700**

25

includes a first wheel support **1705**, and a second wheel support **1710** that is spaced apart from the first wheel support **1705**. In the embodiment shown in FIG. **32**, the first wheel support **1705** is connected to the second wheel support **1710** by a support bar **1706** that extends between the respective rear portions of the first and second wheel supports **1705**, **1710**.

In particular embodiments of the invention, the first and second wheel supports **1705**, **1710** are each supported by one or more load cells **1771**, **1773**, **1785**, **1790**. For example, in the embodiment shown in FIG. **32**, the second wheel support **1710** is supported by first and second load cells **1771**, **1773** that are adapted to cooperate to weigh items that are supported by the second wheel support **1710**. Similarly, in the embodiment shown in FIG. **32**, the first wheel support **1705** is supported by third and fourth load cells **1785**, **1790** that are adapted to cooperate to weigh items that are supported by the first wheel support **1705**. Accordingly, in the embodiment shown in FIG. **32**, the first through fourth load cells **1771**, **1773**, **1785**, **1790** cooperate to weigh items that are supported by the first and second wheel supports **1705**, **1710**.

In a particular embodiment, the second wheel support **1710** includes a first front wheel enclosure **1730** adjacent an outer end of the second wheel support **1710**. For example, in the embodiment shown in FIG. **32**, the second wheel support **1710** includes a first wheel enclosure **1730** that includes a plurality of walls **1734**, **1736**, **1740**, **1742**, **1746** that cooperate to form a substantially enclosed area. This substantially enclosed area preferably includes a floor portion **1732** that, for example, may extend between the base portions of the respective walls **1734**, **1736**, **1740**, **1742**, **1746** that define the first wheel enclosure **1730**.

In the embodiment shown in FIG. **32**, the first front wheel enclosure **1730** includes a gap **1744** between at least two of the walls **1734**, **1736**, **1740**, **1742**, **1746** that define the first front wheel enclosure **1730**. The width of this gap **1744** is preferably longer than the width of an outer front wheel of a cart with which the wheel guide apparatus **1700** is configured to be used. For example, in particular embodiments, the gap **1744** is greater than about 25% longer than the width of an outer front wheel of a cart with which the wheel guide apparatus **1700** is configured to be used. In particular embodiments, this allows the outer front wheel of the cart to selectively pass through the gap **1744** and onto the first front wheel enclosure's floor portion **1732** so that the wheel is: (1) supported by this floor portion **1732**; and (2) substantially surrounded by the walls **1734**, **1736**, **1740**, **1742**, **1746** that define the first front wheel enclosure **1730**.

In particular embodiments, at least one, and preferably all, of the walls **1734**, **1736**, **1740**, **1742**, **1746** that define the first front wheel enclosure **1730** are at least about 25% of the height of an outer front wheel of a cart with which the wheel guide apparatus **1700** is configured to be used. In particular embodiments, the first front wheel enclosure's walls **1734**, **1736**, **1740**, **1742**, **1746** cooperate to restrict (and preferably prevent) the rolling movement of a cart wheel (e.g., the outer front wheel of a cart) from: (1) a first position in which the first front wheel enclosure's walls **1734**, **1736**, **1740**, **1742**, **1746** substantially surround the wheel; to (2) a second position in which the first front wheel enclosure's walls **1734**, **1736**, **1740**, **1742**, **1746** do not substantially surround the wheel. In particular embodiments, the wheel guide apparatus **1700** is adapted to only allow a wheel to roll between these first and second positions by rolling through the gap **1744** defined by the first front wheel enclosure's walls **1734**, **1736**, **1740**, **1742**, **1746**.

In a particular embodiment, the second wheel support **1710** includes a second front wheel enclosure **1750** adjacent an

26

inner end of the second wheel support **1710**. For example, in the embodiment shown in FIG. **32**, the second wheel support **1710** includes a second wheel enclosure **1750** that includes a plurality of walls **1746**, **1754**, **1756**, **1706** that cooperate to form a substantially enclosed area. This substantially enclosed area preferably includes a floor portion **1752** that, for example, may extend between the base portions of the respective walls **1746**, **1754**, **1756**, **1706** that define the second front wheel enclosure **1750**.

In the embodiment shown in FIG. **32**, the second wheel enclosure **1750** includes a gap **1758** between at least two of the walls **1746**, **1754**, **1756**, **1706** that define the second front wheel enclosure **1750**. The width of this gap **1758** is preferably longer than the width of an inner front wheel of a cart with which the wheel guide apparatus **1700** is configured to be used. For example, in particular embodiments, the gap **1758** is at least 25% longer than the width of a wheel of a cart with which the wheel guide apparatus **1700** is configured to be used. In particular embodiments, this allows a wheel of the cart to selectively pass through the gap **1758** and onto the floor portion **1752** of the second front wheel enclosure **1750** so that the wheel is: (1) supported by this floor portion **1752**; and (2) substantially surrounded by the walls **1746**, **1754**, **1756**, **1706** that define the second front wheel enclosure **1750**.

In particular embodiments, at least one, and preferably all, of the walls **1746**, **1754**, **1756**, **1706** that define the second front wheel enclosure **1750** are at least about 25% of the height of an inner front wheel of a cart with which the wheel guide apparatus **1700** is configured to be used. In particular embodiments, the second front wheel enclosure's walls **1746**, **1754**, **1756**, **1706** cooperate to restrict (and preferably prevent) the rolling movement of a cart wheel from: (1) a first position in which the second front wheel enclosure's walls **1746**, **1754**, **1756**, **1706** substantially surround the wheel; to (2) a second position in which the second front wheel enclosure's walls **1746**, **1754**, **1756**, **1706** do not substantially surround the wheel. In particular embodiments, the wheel guide apparatus **1700** is adapted to only allow a wheel to roll between these first and second positions by rolling through the gap **1758** between the second front wheel enclosure's walls **1746**, **1754**, **1756**, **1706**.

In various embodiments, the wheel guide apparatus **1700** further includes a rear wheel enclosure **1770**. In the exemplary embodiment shown in FIG. **32**, this rear wheel enclosure **1770** includes a first side wall **1774**, and a second side wall **1776** that is spaced apart from, and positioned substantially parallel to, the first side wall **1774**. Accordingly, the first and second side walls **1774**, **1776** cooperate to define a path that may be traveled by one or more of the rear wheels (e.g., rear swivel wheels) of a cart with which the wheel guide apparatus **1700** is adapted to be used. The rear wheel enclosure **1770** may further include a floor surface **1772** that extends between the bottom edges of the first and second side walls **1774**, **1776**.

In the embodiment shown in FIG. **32**, the rear wheel enclosure **1770** further includes a wheel stop **1780** that is adapted for stopping the inner rear wheel of a cart when the inner rear wheel of the cart is adjacent a desired target position (e.g., which may occur when the cart is in a desired "loaded" position adjacent the wheel guide apparatus **1700**). As shown in FIG. **32**, in various embodiments, the rear wheel enclosure **1770** further includes a wheel lock **1800** for maintaining a cart's inner rear wheel in this target position. In particular embodiments, this wheel lock **1800** is in substantially the same general physical configuration as the wheel locking mechanism shown in FIGS. **7A** and **7B**.

In various embodiments, the wheel lock **1800** includes a locking mechanism **1820** that is adapted for selectively maintaining the wheel lock **1800** in a locked orientation. It should be understood that any suitable wheel locking mechanism may be used for this purpose. For example, the locking mechanism **1820** shown in FIG. **32** includes a latching mechanism for selectively maintaining the wheel lock **1800** in a locked orientation. In the embodiment shown in FIG. **33**, the locking mechanism **1820** is mechanically linked (e.g., via a bicycle brake cable **1825**) to a foot pedal **1835** that may be used to selectively unlock the wheel lock **1800** (e.g., by selectively unlatching the latching mechanism).

In particular embodiments, the rear wheel enclosure's first and second side walls **1774**, **1776** each define an outer end, and a gate **1850** is pivotably mounted adjacent the outer end of the second side wall **1776**. In various embodiments, the gate **1850** is a one-way gate that is pivotably mounted so that it may swing outwardly away from the second side wall **1776**, but not inwardly toward the second side wall **1776**. In various embodiments, the gate **1850** is positioned so that, when the gate **1850** is in a neutral position: (1) the gate **1850** is substantially perpendicular to the second side wall **1776**; and (2) the gate **1850** extends adjacent a threshold of the rear wheel enclosure **1770**. In particular embodiments, the gate **1850** extends between about 10% and 20% of the distance between the outer ends of the first and second walls **1774**, **1776**.

In various embodiments, rather than a gate, the wheel guide apparatus **1700** includes a fixed barrier **1851** (See FIG. **38**) for obstructing the entry of a wheel into the rear wheel enclosure Ramps and Wheel Guides

As shown in FIG. **33**, in various embodiments of the invention, the wheel guide apparatus **1700** includes: (1) a first front wheel guide **1900** that is adapted for guiding the outer front wheel of a cart into the first front wheel enclosure **1730**; (2) a second front wheel guide **1950** that is adapted for guiding the inner front wheel of the cart into the second wheel enclosure **1750**; and (3) a rear wheel guide **2005** that is adapted for facilitating the movement of the cart's rear wheels into the rear wheel enclosure **1770**. The first and second front wheel guides **1900**, **1950**, and the rear wheel guide **2005** are described in greater detail below.

First Front Wheel Guide

In particular embodiments of the invention, the first front wheel guide **1900** includes: (1) a first, substantially vertical side wall **1910**; (2) a second, substantially vertical side wall **1915** that is spaced apart from, and substantially parallel to, the first side wall **1910**; and (3) a floor portion **1905** that extends between the respective bottom edges of the first and second side walls **1910**, **1915**. In particular embodiments, such as the embodiment of FIG. **33**, the floor portion **1905** is in the form of a ramp, and the first and second side walls **1910**, **1915** are positioned adjacent opposite lateral sides of the ramp **1906** to prevent a cart wheel from rolling off of the ramp as it rolls from a lower end of the ramp to an upper end of the ramp.

In particular embodiments, the first side wall **1910** is spaced apart from the second side wall **1915** by a distance that is equal to between about 100% and about 150% (and preferably between about 110% and about 130%) of the width of an outer front wheel of a cart with which the wheel guide apparatus **1700** is adapted to be used. This may serve to prevent the wheel from moving laterally adjacent the first front wheel guide **1900** as the wheel moves up the ramp.

In particular embodiments, the upper end of the first front wheel guide **1900** is positioned adjacent the gap **1744** in the walls that define the first wheel enclosure **1730**, and the lower

end of the first front wheel guide **1900** is positioned adjacent a floor that is supporting the wheel guide apparatus **1700**.

In various embodiments, such as the embodiment shown in FIG. **33**, the first front wheel guide **1900** includes a staging platform **1930** (e.g., a substantially horizontal staging platform) that extends between the upper end of the ramp and the threshold of the gap **1744** in the walls that define the first wheel enclosure **1730**. In particular embodiments, this staging platform **1930** is sufficiently wide to support a cart wheel (e.g., the outer front wheel of a cart) before the cart wheel rolls into the first front wheel enclosure **1730**.

In particular embodiments, the first wheel guide includes an inner threshold that is adjacent an inner end of said first wheel guide (e.g., immediately adjacent the gap **1744** in the walls that define the first wheel enclosure **1730**) that is spaced apart from an inner lateral edge of the wheel guide apparatus' gate **1850** (See FIG. **33**) by a distance that is about equal to, or less than, the distance between: (a) an axis of rotation of the cart's outer front wheel **222**; and (b) a swivel axis of the cart's outer rear wheel **224**. Similarly, in an embodiment such as the embodiment shown in FIG. **38**, the first wheel guide includes an inner threshold that is adjacent an inner end of said first wheel guide (e.g., immediately adjacent the gap **1744** in the walls that define the first wheel enclosure **1730**) that is spaced apart from an inner lateral edge of the wheel guide apparatus' wheel barrier **1851** by a distance that is about equal to, or less than, the distance between: (a) an axis of rotation of the cart's outer front wheel **222**; and (b) a swivel axis of the cart's outer rear wheel **224**.

Second Front Wheel Guide

In particular embodiments of the invention, the second front wheel guide **1950** includes: (1) a ramp **1955**; and (2) a support platform **1960**. In particular embodiments, such as the embodiment of FIG. **33**, the second front wheel guide's ramp **1955** defines: (1) a lower edge **1956** that is disposed adjacent a support surface supporting the wheel guide apparatus **1700**; and (2) an upper edge **1957** that is at about the same vertical height as the height of the floor **1752** of the second front wheel enclosure **1750**. In particular embodiments, the support platform **1960** defines a substantially horizontal upper support surface that extends from at least about the upper edge **1957** of the ramp **1955** to at least about the threshold of the gap **1758** defined by the walls of the second front wheel enclosure **1750**. In a particular embodiment, the central axis of the second front wheel guide **1950** forms an angle of between 30 and 60 degrees with the wheel guide apparatus' support bar **1706**.

Rear Wheel Guide

In particular embodiments, such as the embodiment of FIGS. **32** and **33**, the rear wheel guide comprises a ramp **2005** that defines: (1) a lower edge that is disposed adjacent a support surface supporting the wheel guide apparatus **1700**; and (2) an upper edge that is disposed adjacent an outer edge of the rear wheel enclosure **1770** at about the same vertical height as the height of the floor **1772** of the rear wheel enclosure **1770**. In particular embodiments, the ramp is about the same width as the opening **1781** in the rear wheel enclosure **1770**.

Operation of the Wheel Guide Apparatus

An example of the general operation of the wheel guide apparatus **1700** of FIGS. **32-37** will now be described. This example pertains to the use of the wheel guide apparatus **1700** with a cart that has two at least substantially fixed (e.g., non-swiveled) front wheels, and two swiveled rear wheels. However, it should be understood that similar techniques may

29

be used in conjunction with carts having other combinations and types of wheels (e.g., two front swiveled wheels, and two rear swiveled wheels).

To use one embodiment of the invention, a user first positions the cart **200**, as shown in FIG. **39**, so that: (1) the cart's outer front (e.g., fixed) wheel **222** is in-line with the lower front edge of the first front wheel guide **1900** (e.g., so that the outer front wheel **222** is oriented to roll between the first wheel guide's first and second vertical walls **1910**, **1915**); and (2) the cart's inner front (e.g., fixed) wheel **221** is in-line with the lower front edge of the second wheel guide **1950** (e.g., so that the inner front wheel is oriented to roll onto the second wheel guide's ramp **1955**). The user then pushes the cart **200** toward the first and second wheel enclosures **1730**, **1750** so that, as shown in FIGS. **39** and **40**: (1) the outer front wheel **222** rolls up the ramp defined by the first wheel guide's floor portion **1905**; and (2) the inner front wheel **221** rolls up the second wheel guide's ramp **1955** and onto the second wheel guide's support platform **1960**.

The user then continues pushing the cart **200** toward the first and second wheel enclosures **1730**, **1750** until the outer front wheel **222** (e.g., an outer edge of the outer front wheel **222**) engages a wheel stop portion of one of the walls (e.g., an outside wall **1736**) that defines the first wheel enclosure **1730**. For example, as shown in FIG. **41**, the user continues pushing the cart **200** toward the first and second wheel enclosures **1730**, **1750** until the outer edge of the outer front wheel **222** engages an inner surface of a first wall **1736** of the first wheel enclosure **1730** that is substantially parallel to, and offset from, a second wall **1746** of the first wheel enclosure **1730** by a distance of between about 100% and about 125% of the diameter of the outer front wheel **222**. In a preferred embodiment, the first wall **1736** of the first wheel enclosure **1730** is offset from the second wall **1746** of the first wheel enclosure **1730** by a distance that is about equal to the diameter of the cart's outer front wheel **222**.

Next, the user pushes the rear end of the cart **200** toward the rear wheel enclosure **1770**, which causes the cart's rear wheels **223**, **224** to rotate from (1) a first orientation in which the cart's rear wheels **223**, **224** are substantially parallel to the cart's front wheels **221**, **222** (see FIG. **40**); to (2) a second orientation in which the cart's rear wheels **223**, **224** are oriented to travel onto the upper surface of the rear wheel enclosure **1770**. In particular embodiments, when the cart's rear wheels **223**, **224** are in this orientation, the cart's rear wheels **223**, **224** are substantially perpendicular to the wheel guide apparatus' support bar **1706**.

The user then continues pushing the rear end of the cart **200** toward the second wheel stop **1780**, which, as shown in FIG. **41**, causes: (1) the cart's rear wheels **223**, **224** to move toward the lower front edge of the ramp defined by the floor of the rear wheel guide **2005**; (2) the cart's outer front wheel **222** to rotate about a vertical axis that extends through the center of the cart's outer front wheel **222**; and (3) the cart's inner front wheel **221** to move further along the second wheel guide **1950** toward the second wheel enclosure **1750**.

Next, the user continues pushing the rear end of the cart **200** toward the second wheel stop **1780**, which, as shown in FIG. **42**, causes: (1) the cart's inner rear wheel **223** to roll up the rear wheel guide **2005** and into the rear wheel enclosure **1770**; and (2) the cart's inner front wheel **221** to roll into the second wheel enclosure **1750**.

The user then continues pushing the rear end of the cart **200** toward the second wheel stop **1780**, which, as shown in FIG. **43**, causes: (1) the inner rear wheel **223** to: (a) roll onto the wheel lock **1800**, causing the wheel locking mechanism **1820** to lock the wheel lock **1800** in place; and (b) engage the

30

second wheel stop **1780** (in various embodiments, the second wheel stop **1780** and the wheel lock **1800** cooperate to lock the inner rear wheel **223** in a "locked" position adjacent the second wheel stop **1780**); (2) the outer rear wheel **224** to move into the rear wheel enclosure **1770**; (3) the inner front wheel **221** to engage a wall **1754** of the second wheel enclosure **1750**; and (4) the outer front wheel **222** to rotate into a particular "locked" position in which it is disposed between: (a) the first wall **1736** of the first wheel enclosure **1730**, and (b) the second wall **1746** of the first wheel enclosure **1730**.

In particular embodiments, when the outer front wheel **222** is in this particular "locked" position, a first end of the outer front wheel **222** is disposed immediately adjacent the first wall **1736** of the first wheel enclosure **1730** and a second end of the outer front wheel **222** is disposed immediately adjacent the second wall **1746** of the first wheel enclosure **1730**. In various embodiments, when the outer front wheel **222** is in this particular "locked" position: (1) the first end of the outer front wheel **222** engages the first wall **1736** of the first wheel enclosure **1730**; and (2) the second end of the outer front wheel **222** engages the second wall **1746** of the first wheel enclosure **1730**.

In various embodiments, when the outer front wheel **222** and the inner rear wheel **223** are in their respective "locked" positions noted above: (1) the outer front wheel **222** is prevented from moving laterally in relation to the wheel guide apparatus **1700** by the first wheel enclosure's first and second walls **1736**, **1746**; and (2) the inner rear wheel **223** is prevented from moving away from the second wheel stop **1780** by the wheel locking mechanism **1800**. As a result, the cart **200** is in a "locked" orientation in which the cart **200** is locked in at least a substantially fixed (e.g., a fixed) position relative to the wheel guide apparatus **1700**.

As an aside, in particular embodiments, when the outer front wheel **222** and the inner rear wheel **223** are in their respective "locked" positions noted above, the cart's front wheels **221**, **222** are substantially perpendicular to (e.g., perpendicular to) the cart's rear wheels **223**, **224**.

To remove the cart **200** from the wheel guide, a user first unlocks the wheel lock **1800** by, for example, stepping on a brake release pedal **1835** adjacent the wheel guide apparatus **1700**. After the wheel lock **1800** is unlocked, the user pulls the rear end of the cart **200** away from the second wheel stop **1780**, which causes the cart's rear wheels **223**, **224** to swivel about 180 degrees and then roll away from the second wheel stop **1780**. This causes the cart **200** to rotate about a vertical axis that extends through the center of the cart's outer front wheel **222** until: (1) the cart's inner front wheel **221** is disposed on the second wheel guide **1950**; and (2) the outer front wheel **222** is aligned to roll onto the first wheel guide **1900**. The user then pulls the cart **200** away from the first and second wheel enclosures **1730**, **1750**, which causes: (1) the cart's outer front wheel **222** to roll down and off of the first wheel guide **1900**; and (2) the cart's inner front wheel **221** to roll down and off of the second wheel guide **1950**. The user may then roll the cart **200** away from the wheel guide apparatus **1700**.

Cart Guide Using a Cart's Body to Guide the Cart's Wheels

In various embodiments of the invention, a cart guide may be used to guide a cart into a desired target position by engaging the cart's body and thereby guiding the movement of the cart's body as the cart rolls into a target position. In a particular embodiment, the cart guide first engages the body of the cart and restricts the movement of the cart to a particular, substantially linear, path. Next, while the cart guide continues to engage the cart, the user then moves the cart along the particular substantially linear path until: (1) the cart's

31

outer front wheel—which is preferably a substantially fixed (e.g., fixed) wheel—is in a particular first staging position; (2) the cart’s inner front wheel—which is also preferably a substantially fixed (e.g., fixed) wheel—is in a particular second staging position; and (3) the cart guide is in a “rotation only” mode, in which the cart guide restricts the movement of the cart to rotating about a particular axis of rotation (e.g., an axis of rotation that is adjacent the cart’s outer front vertical edge). The user then rotates the cart about this particular axis of rotation until the cart is in the target position.

A cart guide **2200** according to a particular embodiment of the invention is shown in FIGS. **44-49**. This cart guide **2200** includes a substantially U-Shaped cart bracket **2220** that is adapted for engaging and restricting the movement of a cart, a cart bracket support **2227** that is adapted for supporting the cart bracket **2220**, and a cart bracket support guide **2207** for guiding the movement of the cart bracket **2220** along one or more particular paths. The structure and operation of these components is described in greater detail below.

Cart Bracket

As may be understood from FIG. **44**, in particular embodiments, the cart bracket **2220** is substantially U-shaped and includes: (1) a substantially planar base portion **2230**; (2) a substantially planar first side member **2232** that extends outwardly from a first end of the base portion **2230**; and (3) a substantially planar second side member **2234** that extends outwardly from a second end of the base portion **2230**. In particular embodiments, the first and second side members **2232**, **2234** are substantially parallel to and spaced apart from one another adjacent the base portion **2230** by a distance that is preferably about equal to the width of the front portion of a cart with which the cart bracket **2220** is adapted to be used. In various embodiments, the first and second side members **2232**, **2234** each extend outwardly from a front surface of the cart bracket’s base portion **2230**.

Cart Bracket Support

In the embodiment shown in FIG. **44**, the cart guide **2200** includes a substantially planar, L-shaped cart bracket support **2227** for supporting the cart bracket **2220**. In this embodiment, the cart bracket support **2227** comprises a substantially planar base portion **2225** that extends outwardly from a rear surface of the cart bracket’s base portion **2230**. In particular embodiments, the base portion **2225** of the cart bracket support **2227** is substantially perpendicular to the rear surface of the cart bracket’s base portion **2230**.

In various embodiments, such as the embodiment of FIG. **44**, the cart bracket support **2227** further includes a substantially planar guide interface member **2229** that cooperates with the cart bracket support’s base portion **2225** to form a substantially planar, substantially L-shaped structure. In various embodiments, the cart bracket support **2227** is attached adjacent a rear surface of the cart bracket’s base portion **2230** so that the cart bracket support **2227** is in a substantially vertical orientation, and so that the guide interface member **2229** extends downwardly from a rear bottom edge of the cart bracket support’s base portion **2225**.

Cart Bracket Support Guide

An exemplary cart bracket support guide **2207** is shown in FIG. **44**. In this embodiment, the cart bracket support guide **2207** includes: (1) an elongate linear guide portion **2215** that is adapted for guiding the cart bracket support **2227** (and also the cart bracket **2220**) along a pre-determined linear path, and (2) a substantially circular rotational guide portion **2205** that is adapted for guiding the cart bracket support **2227** (and also the cart bracket **2220**) along a substantially circular rotational path.

32

In the embodiment shown in FIG. **44**, the elongate linear guide portion **2215** defines an elongate guide opening **2216** having a width that is about equal to the thickness of the cart bracket support’s guide interface member **2229**. Accordingly, the linear guide portion **2215** is adapted to receive the guide interface member **2229** within its guide opening **2216** so that the cart bracket support **2227** (and also the cart bracket **2220**) are free to slide adjacent the linear guide portion along a pre-determined linear path defined by the guide opening **2216**.

In the embodiment shown in FIG. **44**, the substantially circular rotational guide portion **2205** defines a substantially circular guide opening **2211** having a diameter that is about equal to a lateral width of the cart bracket support’s guide interface member **2229**. In particular embodiments, the substantially circular guide opening **2211** is in communication with the elongate guide opening **2216**. As shown in FIGS. **44** and **45**, this allows the cart bracket support **2227** (and also the cart bracket **2220**) to slide along the upper surface of the linear guide portion **2215** until the guide interface member **2229** moves from within the elongate guide opening **2216** and into the substantially circular guide opening **2211**. After the guide interface member **2229** moves entirely out of the elongate guide opening **2216** and into the substantially circular guide opening **2211** (e.g., so that the lateral sides of the guide interface member **2229** are adjacent opposite inner surfaces of the rotational guide portion **2205**), the cart bracket support **2227** (and also the cart bracket **2220**) may rotate adjacent the rotational guide portion **2205** about the center of the circular guide opening **2211**. This is depicted in FIGS. **45** and **46**.

In particular embodiments, the cart bracket support guide **2207** is mounted (e.g., substantially fixedly mounted), as shown in FIG. **47**, so that the linear guide portion **2215** of the cart bracket support guide **2207** forms a pre-determined angle (e.g., of between 20 and 45 degrees) with the support bar **2106** that extends between the rear surfaces of the scale’s first and second support surfaces **2105**, **2110**. Any suitable mechanism may be used for mounting the cart bracket support guide **2207**.

Operation of the Cart Guide

The operation of the exemplary cart guide **2200** of FIGS. **44-46** is shown in FIGS. **47-49**. In this example, the cart guide **2200** is used to position a cart **200** having two front, substantially fixed (e.g., fixed), wheels **221**, **222**, and two rear, swiveled wheels **223**, **224**. In particular, the cart guide **2200** is used to: (1) position the cart’s rear swiveled wheels **223**, **224** onto a first support surface **2105** of a scale **2103**; and (2) position the cart’s front, substantially fixed wheels **221**, **222** onto the scale’s second support surface **2110**. The first and second support surfaces **2105**, **2110** of the scale **2103** are connected by a connecting member **2106**.

In this example, a wheel support portion **2150** and a ramp **2152** are provided adjacent the first support surface **2110** to facilitate the movement of the cart’s front wheels **221**, **222** from a floor surface adjacent the scale’s second support surface **2110** onto the scale’s second support surface **2110**. In particular embodiments, the wheel support portion **2150** is substantially horizontal and extends between the upper edge of the ramp **2152** to about the perimeter of the scale’s second support surface **2110**. The front wheel support portion **2150** serves to facilitate the movement of the cart’s first wheels **221**, **222** from the upper portion of the ramp **2152** onto the scale’s second support surface **2110**. In particular embodiments, the upper surface of the substantially horizontal wheel support portion **2150** is a reduced friction (e.g., smooth) surface, which allows the cart’s front wheels **221**, **222** to slide relative to the substantially horizontal wheel support portion

33

2150. Similarly, in various embodiments, the upper surface of the scale's second support surface 2110 is a reduced friction (e.g., smooth) surface, which allows the cart's front wheels 221, 222 to slide into position on the second support surface 2110.

To use the cart guide 2200, a user first positions the cart bracket 2220, as shown in FIG. 44, so that the cart bracket support's guide interface member 2229 is positioned adjacent an outer end 2217 of the linear guide portion 2215 of the cart bracket support guide 2207. The user then positions the cart 200 as shown in FIG. 47 so that the cart's lateral sides are respectfully substantially in-line with, and substantially parallel to, the inner sides of the cart bracket's the first and second side members 2232, 2234. The user then pushes the cart 200 toward the cart bracket 2220 until the cart's front edge engages the cart bracket's base portion 2230. In this "cart docked" orientation, the cart bracket's first and second side members 2232, 2234 engage respective side walls of the cart 200. As a result, the cart 200 is restricted from moving laterally relative to the cart bracket 2220 and from rotating relative to the cart bracket 2220.

Next, while maintaining the cart 200 in a "cart docked" orientation, the user pushes the cart 200 toward the cart guide's rotational guide portion 2205, which causes the cart bracket support's guide interface member 2229 to slide relative to the upper surface of the linear guide portion 2215 of the cart bracket support guide 2207 (e.g., as shown in FIGS. 44 and 45, and in FIGS. 47 and 48) until the guide interface member 2229 moves from within the elongate guide opening 2216 into the substantially circular guide opening 2211 (See FIGS. 44 and 45). After the guide interface member 2229 moves entirely out of the elongate guide opening 2216 and into the substantially circular guide opening 2211 (e.g., so that the lateral sides of the guide interface member 2229 are adjacent opposite inner surfaces of the rotational guide portion 2205—See FIGS. 45 and 48), the user pushes the rear end of the cart 200 toward the scale's first support surface 2105. This causes the cart bracket support 2227 (and also the cart bracket 2220) to rotate adjacent the rotational guide portion 2205 about the center of the circular guide opening 2211. (See FIGS. 46 and 49). As a result, the cart bracket 2220 guides: (1) the sliding rotational movement of the cart's front, substantially fixed wheels 221, 222 from atop the substantially horizontal wheel support portion 2150, and onto the scale's second support surface 2110, as shown in FIGS. 48 and 49; and (2) the rolling movement of the cart's swiveled wheels 223, 224 onto the scale's first support surface 2105, as is also shown in FIGS. 48 and 49. Once the cart's front and rear wheels 221-224 are fully supported by the scale's first and second support surfaces 2105 and 2110, the cart may be weighed.

To remove the cart from its position on the scale 2103, the user simply reverses the steps outlined above.

It should be understood, in light of this disclosure, that various embodiments of the cart guide may be used, for example, for positioning a cart onto a scale within a dispenser, or within any other suitably dimensioned enclosure. It should also be understood in light of this disclosure that a variety of other suitable mechanisms may be used for guiding the cart's wheels along a predetermined path by restricting the movement of the cart's body.

Conclusion

Many modifications and other embodiments of the invention will come to mind to one skilled in the art to which this invention pertains having the benefit of the teachings presented in the foregoing descriptions and the associated drawings. For example, as will be understood by one skilled in the

34

relevant field in light of this disclosure, the invention may take form in a variety of different mechanical and operational configurations. In addition, although various aspects of the invention are described above in the context of a dispenser (e.g., an automated dispenser), the invention may be implemented in a variety of different contexts. For example, the invention may be embodied in cartridge storage systems that are adapted for: (1) loading a storage cartridge with items to be stored; and (2) moving the loaded storage cartridge into a loaded position within a secure storage cabinet. In addition, although many of the embodiments of the invention described herein were described in the context of loading a storage cartridge having a pair of fixed wheels and a pair of swiveled wheels, it should be understood that the techniques and apparatuses described herein may be applied, for example, to any wheeled device having any combination of wheels (e.g., fixed and/or swiveled wheels). Therefore, it is to be understood that the invention is not to be limited to the specific embodiments disclosed and that modifications and other embodiments are intended to be included within the scope of the appended claims. Although specific terms are employed herein, they are used in a generic and descriptive sense only and not for the purposes of limitation.

What we claim is:

1. A cart enclosure configured for housing a cart, the cart comprising a cart body, a first fixed front wheel secured to the cart body and a second fixed front wheel secured to the cart body, and one or more swiveling rear wheels secured to the cart body, the cart enclosure comprising:

a housing defining an access opening and an interior portion that is accessible through the access opening and dimensioned for receiving the cart; and

a cart positioning assembly disposed at least partially within the housing and configured for facilitating the insertion of the cart into the housing, the cart positioning assembly comprising:

a first platform configured for supporting the fixed front wheels of the cart when the cart is positioned within the interior portion of the housing;

a second platform configured for supporting the swiveling rear wheels of the cart when the cart is positioned within the interior portion of the housing;

a first cart stop comprising one or more walls defining a first front wheel enclosure on the first platform and a second front wheel enclosure on the first platform; the first cart stop being configured to:

engage a front portion of the cart as the front portion of the cart is inserted through the access opening and into the interior portion of the housing in a first direction,

stop movement of the cart in the first direction such that the first fixed front wheel is positioned within the first front wheel enclosure, and

permit the first fixed front wheel to rotate with the cart, within the first front wheel enclosure, and about a vertical axis extending through the first fixed front wheel such that a rear portion of the cart can be inserted in a second direction through the access opening and into the interior portion of the housing and the second fixed front wheel can be inserted into the second front wheel enclosure; and

a second cart stop comprising one or more walls configured to:

engage the rear portion of the cart as the rear portion of the cart is inserted through the access opening and into the interior portion of the housing in the second direction; and

stop movement of the cart in the second direction when the cart is positioned within the interior portion of the housing and the swiveling rear wheels are positioned on the second platform.

2. The cart enclosure of claim 1, wherein the first cart stop 5 is disposed proximate a first lateral side of the housing's interior portion and wherein the second cart stop is disposed adjacent a second lateral side of the housing's interior portion.

3. The cart enclosure of claim 1, wherein the housing 10 comprises a rear wall, a first side wall, and a second side wall; wherein the first cart stop and the second cart stop are configured to prevent the cart from engaging the rear wall, first side wall, and second side wall of the housing during insertion of the cart into the housing's interior 15 portion.

4. The cart enclosure of claim 1, wherein at least one of the one or more walls of the first cart stop is configured to engage at least one of the one or more fixed front wheels of the cart.

5. The cart enclosure of claim 1, wherein at least one of the 20 one or more walls of the second cart stop is configured to engage at least one of the one or more swiveling rear wheels of the cart.

6. The cart enclosure of claim 1, further comprising a scale 25 disposed within the interior portion of the housing and configured for weighing the cart when the cart is positioned within the interior portion of the housing and on at least one of the first platform or the second platform.
